STRINDBERG, strĭnd'bĕry', AUGUST (1849—). A Swedish novelist, dramatist, and miscellaneous writer, the most prominent exponent in Swedish literature of the modern realistic tendency. He was born in Stockholm, and after some success as a dramatic author became at once more widely known through his novel *Röda rummet* (The Red Room, 1879), satirical sketches of the literary and artistic world. In the same vein was *Det nya riket* (The New Kingdom, 1882), which caused such violent discussion on the part of the reactionary journalistic faction as to induce its author to repair to foreign parts, principally Paris, Germany, and Switzerland. Since 1897 he settled again in Sweden. His other novels include *Hemsöborna* (The Natives of Hemsö, 1887), *Skärkarlslif* (Life on the Skerries, 1888), and *I Hafsbandet* (Sea-girt, 1890). Worthy of notice are also several collections of short stories, to wit: *Från Fjerdingen och Svartbäcken* (From Fjerdingen and Svartbäcken, 1877); *Giftas* (Marriages, 1884), which treated satirically of the relation between the sexes in the present age, and which involved him in a lawsuit for alleged irreverent attacks on religious institutions; and *Utopier i verkligheten* (Utopias Realized, 1885), advocating the solution of the labor question from the socialist point of view. Of his dramas *Mäster Olof* (1872) constituted his first stage success and was followed by *Gillets hemlighet* (The Secret of the Guild, 1880), *Herr Bengt's hustru* (Mr. Bengt's Wife, 1882), *Fadren* (The Father, 1887), and *Fröken Julie* (Miss Julia, 1888). Among his other works are *Svenska folket i helg och söken* (The Swedish People in Every Walk of Life, 1882), on which was based the series of seventeen stories *Svenska öden och äfventyr* (Swedish Destinies and Adventures, 1882-90), and *Gamla Stockholm* (Old Stockholm, 1882), in collaboration with Claes Lundin. He published an autobiography entitled *Tjensteqvinnans son* (The Servantmaid's Son, 1886). Consult Hansson, *Das junge Skandinavien* (Dresden, 1891), and Brandes, *Menschen und Werke* (Frankfort, 1894).

STRING (AS. *strenge*, OHG. *strang*, Ger. *Strang*, string, either from AS. *strang*, OHG. *strengi*, Ger. *streng*, strong, or connected with Lat. *stringere*, to draw tight, Gk. *στραγγός*, *strangos*, twisted). The strings of musical instruments are made either from silk, from the entrails of sheep, or from metal. Formerly the metal strings were made of brass or copper, but now they are generally made of steel (for the pianoforte). For the string-instruments (violin, guitar) gut strings are generally used. The thinner the string the higher is the pitch. Excessive thickness for the lower strings is avoided by winding them with thin copper or silver wire. Recently strings, especially those which are overspun, have been manufactured from silk. For the violin the highest or E string is also sometimes made of silk, but its tone quality is inferior to that of a gut string. The silk strings are chiefly used by violinists for the purpose of practicing in warm weather, when the moisture of the fingers causes the gut strings to snap in a short time. See VIOLIN.

STRINGED INSTRUMENTS. See MUSICAL INSTRUMENTS.

STRINGEN'DO (It., drawing tight, compressing). A term used in music to denote a rather sudden acceleration in the time.

STRINGHALT (corruption of *spring* + *halt*, lame). A peculiar catching up of the horse's legs, usually the hind ones. It is most noticeable when the animal is first brought out of the stable, when he is excited, or made to turn suddenly round; it is a form of chorea or Saint Vitus's dance. It does not interfere with usefulness, and is difficult to treat. When due to local injury the habit may be corrected by local treatment.

STRINGHAM, strĭng'am, SILAS HORTON (1798-1876). An American naval officer, born at Middletown, N. Y. He was appointed midship-

man in the navy in 1809, served on the frigate *President* in her conflict with the *Little Belt*, and in the engagement in which she was captured by a British squadron; fought in the war with Algiers, and served on the *Hornet* against the West India pirates. In 1847, as commander of the *Ohio*, he assisted in the bombardment of Vera Cruz. When the Civil War began he was made flag-officer of the North Atlantic blockading squadron, and in August, 1861, coöperated with Gen. B. F. Butler in the capture of the forts on Hatteras Inlet. In the following month he asked to be relieved of command, probably because of the criticisms that had been made against him for not following up his success. In 1862 he became a rear-admiral on the retired list.

STRIPPING (from *strip*, AS. *strypan*, Ger. *streifen*, to strip, plunder). A term used to designate the useless rock which overlies a bed of ore, coal, or building stone, and which has to be removed before the mineral or rock desired can be quarried.

STROBEL, strō'b'l, EDWARD HENRY (1855—). An American diplomat, born at Charleston, S. C. He was educated at Harvard. From 1885 to 1890 he was secretary of the United States legation at Madrid, and for a considerable period served also as chargé d'affaires. In 1888-89 he acted as a special diplomatic agent of the United States to Morocco. Returning to the United States, he became in April, 1893, Third Assistant Secretary of State. In April, 1894, he was appointed United States Minister to Ecuador, but later in the year was transferred to Chile, where he remained until 1897. In the latter year he acted as an arbitrator in a dispute between France and Chile, and in 1899 was counsel for Chile before the United States and Chilean Claims Commission. In 1898 he became Bemis professor of international law in the Harvard Law School. In 1903 he was granted leave of absence to accept the post of general adviser to the Government of Siam under a two years' agreement. He published *The Spanish Revolution* (1898).

STROBOSCOPE. An instrument used for studying the motion of a body where by means of a rapid succession of slits or other openings, or its illumination at regular intervals, the eye receives a series of images on the retina. Where these impressions occur with sufficient rapidity the illusion of motion is produced, and advantage of this is taken in certain toys and scientific instruments. In its simplest form the stroboscope, which was first devised by Stampfer and Plateau, consists of a disk or cylinder with a series of slits through which the observer looks at the pictures or moving object. As the disk or cylinder revolves the slits come successively before the eye and through them the observer gets a series of glimpses of the moving object. If each of the pictures represents a successive stage in an action such as the motion of a pendulum, a man or animal running, etc., the illusion of motion is produced, provided that the interval between the glimpses of the pictures is less than the duration of the image on the retina a time, which varies from 1-10 to 1-50 of a second. A simple stroboscope or zoëtrope is illustrated in the article ILLUSION, while under KINETOSCOPE will be found descriptions of some of the more complex apparatus based on this principle. Anschütz (q.v.), a German photographer, who had achieved considerable success at instantaneous photography, made an important application of the stroboscope principle in his "tachyscope," by rotating transparent pictures on a drum or disk, and having them illuminated by the momentary glow produced by the passage of a spark from an induction coil through a Geissler tube. Although the period of discharge is very brief, yet the sparks follow with regularity, and as the successive pictures always occupy the same position relative to the eye of the observer, the illumination appears continuous, and the effect of motion is produced. See ILLUSION; KINETOSCOPE.

STRODTMANN, strōt'män, ADOLF (1829-79). A German author, born at Flensburg. He studied at Kiel, and, while taking part in the insurrection of 1848, was wounded and captured by the Danes. On being set at liberty he published *Lieder eines Gefangenen auf der Dronning Maria* (1848). He resumed study at Bonn under Kinkel, but was suspended on account of his political activity. He then published *Lieder der Nacht* (1850) and a biography of Gottfried Kinkel (1850). He went to Paris, to London, and in 1852 to America, where for four years he was by turns bookseller and journalist in New York City and Philadelphia. Returning to Germany in 1856, he became known as a biographer of Heine and as war correspondent for several newspapers during the Franco-German campaign. He translated much from English writers. His most noteworthy volume in this field is *Amerikanische Anthologie* (1870), a group of successful renderings from American lyric poets.

STROGANOFF, strō'gà-nôf. A family of Russian nobles, descended from ANIKA, a wealthy merchant of Novgorod, who, in the beginning of the sixteenth century, owned extensive salt pits and iron works in the Ural Mountains. His sons YAKOFF and GRIGORI obtained from Czar Ivan IV. important territorial grants and trade monopolies, founded several cities and fortified towns, and in 1574 received a deed of gift for the Siberian territory bordering on their possessions. The conquest was, however, not accomplished until after their death in 1581, by their youngest brother, SEMEN ANIKITCH, with the coöperation of Yermak, ataman of the Don Cossacks, when Western Siberia was subdued within two years and annexed to the Russian crown. The extraordinary privileges granted to the family were taken, in 1722, from the then living representatives, the brothers ALEXANDER, NIKOLAI, and SERGEI, by Peter the Great, who in exchange conferred upon them only the baronial title. A great-grandson of Nikolai was SERGEI GRIGORYEVITCH (1794-1882), the chief promoter of the archæological excavations on the shores of the Black Sea. He founded and endowed a school of design at Moscow, and acted as curator of the Moscow educational district in 1835-47. His sound judgment in the selection of professors, his munificence and liberal spirit, made this the most brilliant period in the history of the University of Moscow.

STRO'MATOP'ORA (Neo-Lat., from Gk. στρῶμα, *strōma*, covering + πόρος, *poros*, pore). An extinct genus of hydroid corals, which formed extensive coral reefs during some periods of Paleozoic time. The colonies formed rounded or

incrusting and sometimes branching masses that show a concentric lamination and an irregular, cellular, microscopic structure. These hydroid corals are found in fossil coral reefs in the Chazy, Niagara, Lower Helderberg, and Onondaga limestones of New York State, and large specimens, which when polished are of great beauty, have been obtained in the Upper Devonian of the Central States.

STROMB (Lat. *strombus*, sort of spiral snail, from Gk. *στρόμβος*, pine-cone, snail, from *στρέφειν*, *strephein*, to turn, twist). A large gastropod mollusk of the family Strombidæ, or more particularly its shell. The species are numerous, and are mostly inhabitants of tropical seas. *Strombus gigas*, the 'queen conch,' is the largest known univalve. It is found in the West Indies, on reefs in shallow water, and is fished both for the table and on account of the shell. Great numbers of the shells are imported into Europe and America, and are sometimes called 'fountain-shell,' from their aptness as garden ornaments. Their chief use, however, is by cameo-makers. Pearls of a delicate pink color are sometimes found in this shell.

STROMBOLI, strôm'bô-lē. A volcanic island belonging to the Lipari Islands (q.v.).

STRONG, Augustus Hopkins (1836—). An American clergyman, educator, and author. He was born at Rochester, N. Y., and graduated at Yale in 1857 and at the Rochester Theological Seminary three years afterwards. He became a Baptist minister, and in 1872 was made president of the Rochester Theological Seminary and professor of biblical theology in that institution. Among his published works are: *Systematic Theology* (1886; 3d ed. 1890); *Philosophy and Religion* (1888); *Great Poets and Their Theology;* and *Christ in Creation and Ethical Monism* (1899).

STRONG, Caleb (1745-1819). A Governor of Massachusetts, born at Northampton in that State. He graduated at Harvard College in 1764, and was admitted to the bar in 1772. During the Revolution he served in the Massachusetts General Court and on the Committee of Safety of his town, and from 1779 till 1780 sat in the Massachusetts Senate. He was a member of the Philadelphia Constitutional Convention of 1787. From 1789 till 1796 he was a United States Senator, and he was Governor of Massachusetts from 1800 till 1807, and again from 1812 till 1816. In politics he was an ardent Federalist, and as such was bitterly opposed to the War of 1812. On June 26, 1812, he issued a proclamation for a public fast on account of the war just declared "against the nation from which we are descended, and which for many generations has been the bulwark of the religion we profess." By the advice of the State Supreme Court he refused to comply with the President's request to call out the State militia to help in the prosecution of the war. In explanation of this refusal he said that to the Governor, not to the President, belonged the power to decide when to call out the militia. Afterwards he placed the militia of the State under a State major-general; was active in other measures looking toward the practical nullification of the national authority; and approved the report of the Hartford Convention (q.v.). He published *Patriotism and Piety; or Speeches and Proclamations of Governor Strong* (1808). His *Life* was written by Alden Bradford (Boston, 1820). Consult also Dwight, *The Strong Family* (Albany, 1871).

STRONG, George Crockett (1832-63). An American soldier, born in Stockbridge, Vt. He graduated at West Point in 1857; was an ordnance officer with the rank of lieutenant on the staff of General McDowell in the first battle of Bull Run, and later served successively on the staffs of Generals McClellan and Butler. He commanded an expedition sent from Ship Island against Biloxi, Miss., in April, 1862, and another sent against Pontchatoula, and was commissioned brigadier-general of volunteers in November, 1862. He commanded a brigade in the operations against Charleston, S. C., in June and July, 1863; made a successful descent on Morris Island on July 10th; and on the 18th of the same month was mortally wounded while gallantly leading the assault on Fort Wagner. A commission as major-general of volunteers was made out to date from the day of the battle. He published *Cadet Life at West Point* (1862).

STRONG, James (1822-94). An American Methodist lay biblical scholar and educator. He was born in New York City and studied medicine for a time, then entered Wesleyan University, Middletown, Conn., graduating 1844. He taught languages at Poultney, Vt., in 1844-46; lived in Flushing, L. I., in 1848-57, teaching privately and acting as president of the Flushing Railroad and president of the village. He was professor of biblical literature and acting president of Troy University in 1858-63; professor of exegetical theology in Drew Theological Seminary, Madison, N. J., 1868-93. He traveled in the East in 1874, and was a member of the Anglo-American Bible Revision Committee, 1871-81. In 1853 he became associated with Dr. John McClintock in the preparation of the *Cyclopædia of Biblical, Theological, and Ecclesiastical Literature* (revised edition 1890), and in 1870 became editor-in-chief. The best-known of his works besides the *Cyclopædia* are *English Harmony and Exposition of the Gospels* (1852), *The Tabernacle of Israel in the Desert* (1888), *Doctrine of a Future Life* (1892), *Exhaustive Concordance of the Bible* (1895), a work upon which he was engaged for thirty-five years. The *Student's Commentary on the Book of Psalms* (1896) was issued posthumously with prefatory memoir by Rev. Henry A. Buttz.

STRONG, Sir Samuel Henry (1825—). A Canadian jurist, born at Poole, England. He went to Canada in 1836 and in 1849 was admitted to the bar. In 1856 he was appointed a member of the commission for consolidating the statutes of Upper Canada and Canada; in 1863 was created Queen's counsel, and in 1869 was made a vice-chancellor of the Court of Chancery. He was called to the Ontario Court of Error and Appeal in 1874, and in 1875 was made puisne judge in the newly constituted Canadian Supreme Court, of which he became Chief Justice in 1892. In 1897 he was sworn of her Majesty's Privy Council.

STRONG, Theodore (1790-1869). An American mathematician, born in Massachusetts. He was educated at Yale, and after graduation (1812) became tutor in mathematics at Hamilton College, and in 1816 professor of mathe-

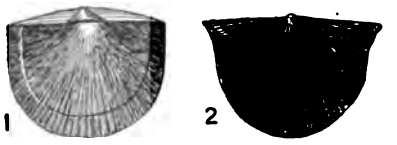
matics. In 1827 he accepted the chair of mathematics and natural philosophy in Rutgers College, a position which he retained till 1862, when he retired from active life. Strong made many important contributions to mathematical science. A new geometrical demonstration of the values of the sines and cosines of the sum and difference of two arcs was given by him in 1818. He also gave a solution of the irreducible case of the cubic equation, and devised a method for the application of the binomial theorem to the extraction of the roots of whole numbers. His two principal systematic works are *A Treatise on Elementary and Higher Algebra* (1859) and *A Treatise on the Differential and Integral Calculus* (1869).

STRONG, William (1808-95). An American jurist, born in Somers, Conn. He graduated at Yale in 1828, and was admitted to the bar in Reading, Pa., in 1832. In 1846 and again in 1848 he was elected to the national House of Representatives as a Democrat; and from 1857 until 1868 he was a justice of the Pennsylvania Supreme Court. From 1870 until 1880 he was associate justice of the United States Supreme Court. He was a member of the Electoral Commission that decided the disputed Presidential election of 1876 and in that capacity contended that Congress had no power to canvass State returns for Presidential electors. He was for many years connected with societies for the advancement of Sunday schools and missionary work.

STRONG, William L. (1827-1900). The last Mayor of New York previous to the formation of Greater New York. He was born in Richland County, Ohio; was a drygoods salesman in Wooster and then in Manchester, Ohio; in 1853 went to New York City, where he engaged in similar business, and in 1869 became the head of the firm of William L. Strong & Co. In politics he was a Republican. From 1895 to 1898 he was Mayor of New York, having been elected on a fusion ticket supported by Republicans and anti-Tammany Democrats.

STRONGBOW. A surname of Richard Fitz Gislebert, Earl of Pembroke, one of the leaders in the Anglo-Norman conquest of Ireland (q.v.).

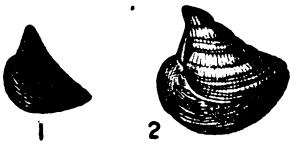
STRONGYLUS (Neo-Lat., from Gk. *στρογγύλος*, round). A genus of nematode worms, parasitic in man and other animals. The only true Strongylus infesting man is *Strongylus bronchialis*. The male usually measures rather more than half an inch, while the female is upward of an inch in length. It is apparently a rather uncommon parasite, as few cases have been reported, though allied species occur in the lungs and air passages of pigs, calves, and sheep. Closely allied to Strongylus is the genus *Eustrongylus*, which contains the species *Eustrongylus gigas*, which is the largest nematode worm at present known to infest man or any other animal, the male measuring a foot in length, and one-fourth of an inch in diameter, while the female is more than three feet, its transverse diameter being fully half an inch. The body is cylindrical, and more or less tinged with redness; the head obtuse, and furnished with a simple oval aperture surrounded by six chitinous nodules. This worm occurs in the kidneys and bladder, sometimes in the abdominal cavity and the omentum, more rarely in the lungs and liver of man and other animals. Fortunately, it is very rare in man; it is said that weasels are the animals in which it is most commonly found.



STRONTIUM (Neo-Lat., from *Strontian*, Argyllshire, Scotland). A metallic element first isolated by Davy in 1808, its earth having been recognized as a distinct chemical substance after Cruikshank (1790), Hope (1792), and Klaproth (1793) had discovered that it gives a peculiar coloration if introduced into a flame. Strontium occurs as the carbonate (strontianite), as the sulphate (celestite), as the silicate in combination with barium and calcium (brewsterite), also in small quantities in other minerals, such as arragonite, calcite, and dolomite. It further occurs in mineral and sea waters, and also in the ashes of certain plants. The metal may be obtained by the electrolysis of the moistened hydroxide or the chloride. Strontium (symbol, Sr; atomic weight, 87.61) is a yellow metal with a specific gravity of 2.5; it melts at a moderate red heat. It is both malleable and ductile, is less electro-positive than calcium and the alkali metals, oxidizes quickly on exposure to the air, and burns brilliantly when heated, forming the oxide. It combines with oxygen to form a monoxide (SrO) and a dioxide (SrO_2). The former is a gray-white, porous, infusible solid that is usually prepared by igniting the nitrate. The hydrate formed by the action of water on the oxide has the property of combining with crystallizable sugar to form a saccharate easily decomposed by carbon dioxide, and hence is extensively used for the separation of sugar from beet-root molasses. The nitrate, which may be prepared by dissolving the carbonate in warm dilute nitric acid and evaporating to crystallization, finds use for pyrotechnic purposes, owing to the red flame with which it burns.

STROPHADES, strŏf'ȧ-dēz (Lat., from Gk. *Στροφάδες*). Two small islands in the Ionian Sea, now Strofadia and Strivali. The name was given from the legend that the sons of Boreas pursued the Harpies to the islands, thence returning (*στρέφειν*, to turn) from their expedition.

STROPHANTHUS (Neo-Lat., from Gk. *στρόφος*, *strophos*, twisted, bent, from *στρέφειν*, *strephein*, to turn, twist + *ἄνθος*, *anthos*, flower). A drug consisting of the seed of Strophanthus hispidus, a climbing African plant of the order Apocynaceæ. From the seed can be obtained its active principle strophanthin, a bitter glucoside. This is a white, amorphous, or crystalline powder, soluble in water or alcohol. The physiological action of the drug is much like that of digitalis (q.v.). It slows the action of the heart, increases its contractility, and increases the arterial tension, though less than digitalis. Its action is more rapid, less protracted, and less certain than that of digitalis. It is also less diuretic, less apt to disturb the stomach, and is not cumulative. In large doses it is a direct poison to the voluntary muscles, which become tonically contracted and pass into a condition resembling *rigor mortis*. Strophanthus is a valuable cardiac stimulant and is used in cases in which digitalis is indicated, but in which, for any reason, it is necessary to substitute another drug. It is also of use when digitalis fails to act. The official tincture is the form generally employed.



STROPHE, strō'fē (Lat., from Gk. *στροφή*, a turning, from *στρέφειν, strephein*, to turn, twist). A term which originally designated the evolutions of the Greek chorus from one position to another in the orchestra; then the portion of the song which accompanied this movement. In its ordinary sense, as applied to Greek and Latin lyric poetry, it designates a combination of rhythmical periods to which a following combination corresponds exactly or very closely; these are known respectively as strophe and antistrophe (q.v.). The name is also often applied to the stanza of modern poetry. See VERSIFICATION.

STRO'PHOME'NA (Neo-Lat. nom. pl., from *στρόφος, strophos*, twisted, bent + *μήνη, mēnē*, crescent). An important genus of fossil long-hinged brachiopods of Paleozoic age, typical of the family Strophomenidæ. The primitive members of this family are characterized by their general semicircular outline, long hinge lines,

1, *Orthothetes Chemungensis* (view from the brachia valve); 2, *Strophomena filitexta* (pedicle valve).

and well-developed cardinal teeth, distinct hinge areas, and low beaks. In the secondary derived members of the group the hinge line shortens, the beak lengthens, the hinge area increases in height, and the articulating processes undergo interesting modifications, while correlated modifications take

1, *Stroptorhynchus pelargonatus* (profile); 2, *Derbya Bennetti* (profile).

place in the interior of the shell. The simplest and earliest member is Rafinesquina (Ordovician), with valves normally concavo-convex dorso-ventrally, and hinge line simple. Strophomena (Ordovician and Silurian) in its embryonic stages has the general form of shell seen in Rafinesquina, but the adults have the valves resupinate or recurved so that the dorsal valve is convex and the ventral valve flat or concave. From Rafinesquina arises a long line of descendants reaching into Carboniferous times. These genetically related types are Strophomena (Ordovician to Silurian), Orthothetes (Silurian to Carboniferous), Derbya (Carboniferous), Stroptorhynchus (Upper Carboniferous to Permian). Consult Hall and Clarke, "An Introduction to the Study of the Genera of Palæozoic Brachiopoda," *Palæontology of New York*, vol. viii., part i. (Albany, 1892).

STROSSMAYER, strŏs'mī-ĕr, JOSEPH GEORG (1815-1905). An Austrian Roman Catholic bishop, born at Eszék, Slavonia. After being educated at Diakovár, Budapest, and Vienna he became professor in the seminary at Diakovár, afterwards Court chaplain in Vienna, and in 1849 Bishop of Diakovár. A leader of the Croatian national party, he promoted the cause of education in various ways, contributed largely to the establishment of the academy and university at Agram, and built the beautiful Romanesque cathedral at Diakovár. He came most prominently into notice at the time of the Vatican Council, in which he was considered the leader of the Inopportunists, or those who considered it inadvisable to define Papal infallibility.

STROTHER, strŏTH'ĕr, DAVID HUNTER (1816-88). An American author and illustrator, born at Martinsburg, W. Va. Educated as an artist, he first became known to the public in 1852 as 'Porte Crayon,' the author of a series of amusing papers published in *Harper's Magazine*, descriptive of travel, scenery, and manners in the South. Many of these were afterwards collected in *The Blackwater Chronicle* (1853) and *Virginia Illustrated* (1857). He entered the Union army as captain in 1861, became colonel, resigned in 1864, and in 1865 was brevetted brigadier-general. After the war he continued to write and sketch for periodicals, and from 1879 to 1885 was Consul-General to Mexico.

STROUD, stroud. A town in Gloucestershire, England, 9 miles south-southeast of Gloucester, at the confluence of the Frome and Slade (Map: England, D 5). It is the centre of the woolen manufactures of Gloucestershire. The water of the Frome is peculiarly adapted for use in dyeing scarlet and other grain colors; and on this account cloth factories and dye works have been built along its banks for a distance of twenty miles. Population, in 1901, 9188. At the Domesday survey Stroud was part of Bisley Parish, from which it separated in 1304.

STROUDSBURG. The county-seat of Monroe County, Pa., 53 miles southeast of Scranton, on the Analomink River, and on the New York, Susquehanna and Western and the Delaware, Lackawanna and Western railroads (Map: Pennsylvania, F 3). It is in a beautiful region. But four miles distant is the famous Delaware Water Gap. In East Stroudsburg is a State Normal School. There are flour and woolen mills. Population, in 1890, 2419; in 1900, 3450.

STROZZI, strôt'sê. A noble Florentine family which first attained prominence toward the end of the thirteenth century. From that time until 1530 they appear as the rivals of the Medici, with whom they shared the great offices of State. At their most flourishing period toward the end of the fifteenth century they numbered eighty heads of families. Then was built from the plans of Benedetto da Majano and Cronaca that famous palace which has been ranked with the Farnese at Rome and the Vendramin at Venice as one of the three finest in Italy. Cosmo I. de' Medici upon his accession in 1537 brought about the fall of the rival house. Various branches of the family took foreign service or settled in Naples, Mantua, and Ferrara.

STROZZI, BERNARDO (1581-1644). An Italian painter (called Il Prete Genovese and Il Capuccino). He was born in Genoa and began to paint at sixteen, but gave up his art to become a Capuchin monk. The necessities of his family required his aid, however, and he was temporarily permitted to leave the monastery in order to give himself again to painting. When he refused to return to the cloister after the death

of his mother and the marriage of his sister he was arrested and imprisoned in the dungeon of his Order for three years, when he escaped to Venice and there worked privately and for the State, decorating the library of Saint Mark's and the churches of San Benedetto and of the Incurabili. His best efforts were portraits.

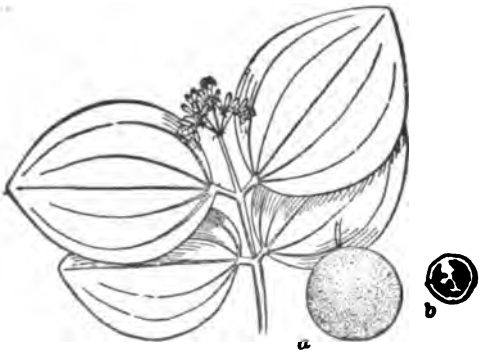
STRUENSEE, strōō'en-zā, JOHANN FRIEDRICH VON, Count (1737-72). A Danish statesman, born August 5, 1737, at Halle, Saxony. He studied medicine, became the physician of King Christian VII. (q.v.) of Denmark (1768), and rose to the highest favor. In 1771 he was made Minister of State with unusual powers. Since the Revolution of 1660 Denmark had been under the domination of the nobility, who as a council of State governed the country. Struensee dissolved the council, and proclaimed the establishment of the ancient royal power. These measures amounted in reality to a revolution, and to a declaration of war against the aristocracy. The Queen and Struensee, in whose hands the whole power now was, chose new ministers, and excluded the feeble Christian entirely from the management of affairs. In opposition to the policy of his predecessors, Struensee endeavored to free Denmark from Russian influence, and to find a natural ally in Sweden. He put the finances in order, reduced the expenditure, freed industry and trade, encouraged education, mitigated the penal laws, and brought order into the administration. Serfdom was partially abolished. The haste with which this revolutionary course was pursued produced a reaction, while the clergy were aroused by Struensee's outspoken skepticism. The Queen and Struensee were accused of criminal relations and the King was prevailed upon, apparently against his will, to sign warrants for the arrest of Struensee. The Minister was accused of having conspired against the person and throne of the King, and of being the lover of the Queen. He was sentenced to death and executed April 28, 1772. Queen Carolina Matilda left Denmark in May, 1772, and died in 1775 in the castle of Celle in Hanover. Consult *Struensee et la cour de Copenhague—mémoires de Reverdil* (Paris, 1858).

STRÜMPELL, strŭm'pel, LUDWIG (1812-99). A German philosopher, born at Schöppenstedt. He studied philosophy at Königsberg, where he was influenced by Herbart, and continued his studies at Leipzig. In 1845 he became professor of philosophy at Dorpat, and after 1872 he held a similar position at the University of Leipzig. He became known as a prominent representative of Herbart's philosophy and published *Erläuterungen zu Herbarts Philosophie* (1834), *Die Hauptpunkte der Herbartschen Metaphysik kritisch beleuchtet* (1840), *Gedanken über Religion und religiöse Probleme* (1888), *Abhandlungen zur Geschichte der Metaphysik, Psychologie und Religionsphilosophie* (1896), and *Vermischte Abhandlungen aus der theoretischen und praktischen Philosophie* (1897).

STRUTT, JOHN WILLIAM. An English physicist. See RAYLEIGH.

STRUTT, JOSEPH (1749-1802). An English antiquary. He studied engraving and painting, but devoted himself mostly to research in the British Museum. Among his works are *The Regal and Ecclesiastical Antiquities of England* (1773); *The Chronicle of England* (1777-78); *Complete View of the Dress and Habits of the People of England from the Establishment of the Saxons in Britain to the Present Time* (1796-99); *Sports and Pastimes of the People of England* (1801); and a curious historical romance, entitled *Queenhoo Hall*, edited and completed by Sir Walter Scott (1808). Strutt's work as antiquary was so well done that it has not yet been superseded. His engravings in the 'chalk' or dotted style are much sought after.

STRUVE, strōō've, FRIEDRICH GEORG WILHELM VON (1793-1864). A Russian astronomer, born at Altona, Germany. He was educated at the University of Dorpat, and appointed to a post in the observatory in 1813, and continued with the utmost assiduity his observation and researches respecting double and multiple stars, adding immensely to our knowledge of these systems. In 1839 he became director of the newly organized observatory at Pulkova, and here he continued again his classic researches concerning double stars. Struve also executed a number of important geodetic operations, such as the triangulation of Livonia, in 1816-19, and the measurement of an arc of the meridian in 1822-52. He published: *Observationes Dorpatenses* (1817-39); *Catalogus Novus Stellarum Duplicium* (1827); *Stellarum Duplicium Mensuræ Micrometricæ* (1831); *Stellarum Fixarum, Imprimis Compositarum Positiones Mediæ* (1852). All these works are fundamental in the history of double-star astronomy. He published also *Arc du méridien entre le Danube et la Mer Glaciale* (1857-60).



STRUVE, GUSTAV VON (1805-70). A German revolutionist, born in Munich. He was an ardent Liberal, and in 1848 took part with Hecker and others in the first revolt in Baden. After the defeat at Staufen he was captured and sentenced to five years of solitary confinement. Released by the Revolutionists in 1849, he became the leader of the Republican Party in the Constituent Assembly of Baden. Forced to flee again, he went first to Switzerland, then to England, and finally, in 1851, to the United States. Here he composed his *Allgemeine Weltgeschichte* (1853), a history of the world from the standpoint of radical republicanism. When the Civil War broke out he served for a time as an officer in the Eighth New York Regiment, but in 1863 returned to Europe, where he lived for a time in Coburg, then in Vienna until his death. Among his numerous other works are: *Das öffentliche Recht des deutschen Bundes* (1846); *Geschichte der drei Volkserhebungen in Baden* (1848); and *Das Revolutionszeitalter* (1860).

STRUVE, OTTO WILHELM (1819—). A Russian astronomer, born at Dorpat. In 1837 he became his father's chief assistant at Pulkova. In 1862 he became the director of Pulkova Observatory, a position which he held till 1889, when he retired to Karlsruhe. In his examination of the northern heavens he discovered 500 binary stars and also determined the parallax of several stars, and observed the variability of the light coming from the nebula of Orion and the several stars hidden in the nebula. He also determined a new value of the precession constant (1841),

calculated the dimensions of the ring of Saturn, determined the mass of Neptune, and made observations on solar velocity and the extent of the corona. Struve wrote: *Uebersicht der Thätigkeit der Nicolai-Hauptsternwarte während der ersten 25 Jahre ihres Bestehens* (1865); *Zum 50-jährigen Bestehen der Nikolai-Hauptsternwarte* (1887); *Observations de Pulkova* (1869-93).

STRYCHNINE, or **STRYCHNIA** (from Lat. *strychnos*, from Gk. *στρύχνος*, *strychnos*, plant of the nightshade kind). A poisonous alkaloid resembling brucine (q.v.), obtained from various species of plants, especially from the seeds of the Saint Ignatius bean and from nux vomica. It occurs in right square octahedrons or prisms, colorless and inodorous, scarcely soluble in water, but easily so in alcohol, ether, and chloroform. Pure sulphuric acid forms with it a colorless solution, which, on the addition of bichromate of potash, acquires an intensely violet hue, speedily passing through red to yellow. If, indeed, the solution is diluted with water while it is red and ammonia is added, it becomes a violet purple, changing to yellow. Another test for strychnine is its action upon animals. In nitric acid it ought, if pure, to form a colorless solution; if the solution is reddish it is a sign that brucine is also present. Strychnine combines with numerous acids, and forms well-marked salts, which are amenable to the same tests as the base itself and are soluble in water. Strychnine is intensely bitter, and will impart this quality to 20,000 times its weight of water. See ANTIDOTES.

STRYCHNOS (Lat., from Gk. *στρύχνος*, *strychnos*, *τρύχνος*, *trychnos*, plant of the nightshade kind). A genus of trees and shrubs of the natural order Loganiaceæ. To this genus belongs *Strychnos Nux-vomica*, an East Indian tree of medium size, whose fruit, which is produced in great abundance, is about the size of a small orange. Its disk-shaped seeds, which are the nux vomica of commerce, yield the alkaloids strychnine and brucine. The wood of the tree is very hard and durable. The clearing-nut and Saint Ignatius bean are produced by species of this genus, to which also belongs the South American tree (*Strychnos toxifera*) from which

NUX VOMICA (*Strychnos Nux-vomica*).
a, fruit; *b*, seed.

curare or woorali is obtained. Another species is the upas tieuté (*Strychnos Tieute*) of Java, a large climbing shrub, whose bark is reputed poisonous. The wood of a climbing species (*Strychnos colubrina*), found in the north of India, is said to cure snake bites. The bark of *Strychnos Pseudo-quina*, a Brazilian species, is used as a substitute for cinchona. The climbing species are provided with curious hooked tendrils by which they attach themselves to trees. Despite the popular ill-repute attached to many of the species, their fruits, especially those of *Strychnos Nux-vomica*, seem to be harmless, since they are often eaten by birds.

STRYJ, strĭ'y'. A town in Galicia, Austria, 40 miles south of Lemberg (Map: Austria, J 2). It has a castle. Its industries include the manufacturing of leather, matches, and iron products. Population, in 1890, 16,515; in 1900, 23,673.

STRY'KER, MELANCTHON WOOLSEY (1851—). An American educator, born at Vernon, N. Y. He graduated at Hamilton College in 1872 and at the Auburn Theological Seminary four years later. Between 1876 and 1892 he was pastor of churches in Auburn, N. Y.; Ithaca, N. Y.; Holyoke, Mass.; and Chicago. In the latter year he was elected president of Hamilton College. His publications include *The Song of Miriam* (1888), a hymnal *Church Song* (1889), *Dies Iræ* (1893), *Lattermath* (1896), and a number of addresses.

STRYPE, JOHN (1643-1737). A Church of England historian and antiquary. He was born in London, studied at Cambridge, entered the Church, and held for many years, with other smaller livings, the rectory of Leyton, in Essex. His works fill 13 large folio volumes. *Ecclesiastical Memorials*, relating to religion and the Church of England under Henry VIII., Edward VI., and Mary, is his best work, forming, with Burnet's more readable *History of the Reformation*, a consecutive and full account of the reformed Anglican Church. As a writer he is heavy, but honest and plodding, and he was a faithful transcriber of the ancient papers he published, which, he says, were all copied with his own hand. His complete works were reprinted with general index by R. F. Laurence (28 volumes, Oxford, 1820-28).

STU'ART, or **STEWART**. A Scotch and English royal family. Its origin is traced to Fitzflaald, a Norman, who accompanied the Conqueror to England. His second son, Walter (d. 1117), entered the service of David I. of Scotland, who conferred large territorial possessions on him, along with the dignity of Steward of Scotland, which became hereditary in his family, and was assumed by his descendants as a surname, some branches of the house later modifying the orthography to Steuart, or the French form Stuart. For seven generations the stewardship continued unbroken from father to son. Walter, the third steward and grandson of the first steward, held, in addition, the office of justiciary of Scotland. Alexander, fourth steward, was Regent of Scotland in Alexander III.'s minority. James, the fifth steward, was one of the six Regents of Scotland after the death of Alexander III.; and Walter, the sixth steward, by his marriage with Marjory, daughter of Robert Bruce, eventually brought the crown of Scotland to his family. His son, Robert, seventh high steward, was Regent from 1338 to 1341, and afterwards during the captivity of his uncle, David II., from 1346 to 1357. On the death of David II., in 1371, he ascended the throne as Robert II., and died in 1390. (For the subsequent history of the royal family see articles ROBERT II. and

III.; JAMES I., II., III., IV., V.; MARY STUART; JAMES I. (of England); CHARLES I. and II.; JAMES II.; MARY II.; and ANNE.) In the person of James II. the line of Stuart was driven from the English and Scottish thrones. The claims of the house were upheld by James's son, the Old Pretender (see STUART, JAMES EDWARD), and by the latter's son, known as the Young Pretender. (See STUART, CHARLES EDWARD.) A brother of the latter was HENRY BENEDICT MARIA CLEMENT, Cardinal York, born 1725. After Culloden (1746) he went to Rome, took orders, and was advanced to the purple by Benedict XIV. in 1747. During his brother's life he was known as Cardinal York; but after his death he assumed the regal style as Henry IX., King of England. The expulsion of Pius VI. from Rome, and other events following upon the French Revolution, drove him to Venice, aged and infirm and reduced to absolute poverty. George III. settled on him an annuity of £4000. He died in 1807 at the age of eighty-two, the last direct descendant in the male line of the royal Stuarts.

The female line of the Stuarts is represented by the descendants of Henrietta Maria, daughter of Charles I., who was married to Philip, Duke of Orleans, brother of Louis XIV. of France. This princess had two daughters, of whom the elder, Mary, was Queen of Charles II. of Spain, and died childless; the younger, Anna Maria, married Victor Amadeus II., Duke of Savoy and King of Sardinia, and was mother of Charles Emmanuel III., King of Sardinia, and grandmother of Victor Amadeus III. of Sardinia. See SAVOY, HOUSE OF.

The branch of the family which the Act of Settlement called to the throne on the death of Queen Anne was descended from the Electress Sophia of Hanover, granddaughter of James I. (VI.) by her mother, the Princess Elizabeth Stuart (q.v.), Electress Palatine and Queen of Bohemia.

The cadets of the House of Stuart, descendants of Robert II., are represented by some of the most noble titles in Scotch and English history. Consult: Stewart, *Historical and Genealogical Account of the Royal Family of Scotland, and of the Surname of Stewart* (Edinburgh, 1739); Noble, *Historical Genealogy of the Royal House of Stewart* (London, 1795); Thornton, *The Stuart Dynasty* (ib., 1890); Gibb and Skelton, *The Royal House of Stuart* (ib., 1890).

STUART, Lady ARABELLA, or ARBELLA (1575-1615). The daughter of Charles Stuart, Earl of Lennox, a younger brother of Lord Darnley (q.v.). She was the next in the line of succession to her cousin James I. of England, and her relationship to Elizabeth gave rise to a number of plots, including one by Sir Walter Ralegh in 1603, to place her on the throne. Several schemes to marry her were defeated by Elizabeth, but in 1610 it was discovered that she had made a secret marriage with William Seymour (q.v.), grandson of the Earl of Hertford. Seymour was imprisoned in the Tower of London and his wife put in the custody of the Bishop of Durham, but she escaped to a French vessel, in which her husband, who had escaped from the Tower, was also to sail. He did not reach it, but escaped in another vessel, while the vessel in which Arabella sailed was captured, and she spent the last five years of her life in the Tower, dying insane. Consult Cooper, *Life and Letters of Lady Arabella Stuart* (1866).

STUART, CHARLES EDWARD LOUIS PHILIP CASIMIR, often called the YOUNG PRETENDER (1720-88). A claimant to the British throne. He was the eldest son of James Edward, known as the Old Pretender, and was born at Rome. After some military service on the Continent, Charles, encouraged by the French Government, decided to make an armed attempt to obtain the British crown. The French aid, however, did not materialize, and Charles landed almost alone on August 2, 1745, on an islet in the Hebrides. The Highland clans flocked to his standard, and Charles pressed on to Perth, where he was joined by Lord George Murray. The troops of the Government were defeated at Prestonpans on September 21, 1745, and Carlisle was taken in November. Lord George Murray completely outmanœuvred his opponents, and soon had a clear road to London. In the first days of December the Highlanders were in Derby. Panic prevailed in London. But England did not rise in behalf of the Stuarts as had been expected, and Murray was cut off from his base of supplies. In consequence the retreat began on December 6, and the Duke of Cumberland pursued. On April 16 (new style April 27), 1746, the rebels were totally defeated at Culloden Moor. From April to September Charles Edward lay concealed in the Highlands and on the Hebrides with a price on his head, and hunted by the soldiers, but safe in the devoted loyalty of the clansmen. He finally reached France after many hairbreadth escapes. Thereafter his life was chiefly marked by its dissoluteness. It seems that he was in London in 1750, and again in 1752 and 1754, in the vain hope of fomenting another rising. In 1772 Charles married Louisa, Princess of Stolberg (see ALBANY, LOUISA MARIA CAROLINE), but she was unable to tolerate his brutality, and they separated in 1780. Thereafter Charles lived chiefly at Florence in the company of a daughter born to him by Miss Walkenshaw, his mistress. He died at Rome. Consult: Ewald, *Life and Times of Prince Charles Stuart, Count of Albany* (London, 1875); Lang, *The Prince Charles Edward* (ib., 1900).

STUART, ELIZABETH (1596-1662). See ELIZABETH STUART.

STUART, GILBERT (1755-1828). An American portrait painter. He was born at Narragansett, R. I., December 3, 1755. He painted his first portraits when thirteen, having had no instruction. In 1770 he was taught by a Scotsman, Cosmo Alexander, who took him to England, but upon Alexander's death Stuart was forced by poverty to return to America after a year's absence. A maturing talent brought him frequent commissions, and thus he was enabled in 1775 to return for further study to England. In London he formed the acquaintance of Benjamin West, who gave him instruction and a home in his own house. After much adversity, during which he supported himself as an organist, he attained a distinguished position. He returned to America in 1792, his impelling motive being to paint the portrait of Washington. He established a studio in New York, but removed to Philadelphia, where the first Washing-

ton portrait was painted in 1795; at a still later period he lived in the city of Washington, and finally in 1806 took up his permanent residence at Boston, where he died. The Stuart portraits of Washington, representing the subject in the later years of his life, are the most famous of both artist and sitter. The first of these, representing the right side of the face, the artist destroyed as unsatisfactory, though six replicas exist; after 1796 he painted the portrait known as the 'Athenæum portrait' (Boston Museum), showing the left side. A full length was painted for the Marquis of Lansdowne in 1796. Nearly forty replicas of his various Washington portraits have been traced. The Historical Societies of Boston, New York, and Philadelphia have many examples of his work, as do the Metropolitan Museum and other American collections.

Stuart was an entirely independent master, who followed neither West nor any other model, but nature alone. Though sometimes deficient in drawing, he was a good colorist, and in his best productions deserves to rank beside Gainsborough. He devoted his chief attention to the heads, which are rendered with force and truth, but rather neglected the rest of the portrait. The list of his sitters includes the first five Presidents of the United States, Edward Everett, John Jay, Jacob Astor, Judge Story, W. E. Channing, Josiah and Edmund Quincy, O. H. Perry, Jerome and Mme. Bonaparte. During his residence in England he painted King George III., also George IV. while Prince of Wales, Louis XVI. of France (at Paris), Mrs. Siddons, Sir Joshua Reynolds, Benjamin West, and a notable picture of "W. Grant Skating in Saint James's Park," which made his reputation in England. Consult Mason, *Life and Works of Gilbert Stuart* (New York, 1879); Caffin, *American Masters of Painting* (New York, 1896).

STUART, Henry Benedict Maria Clement, Cardinal York (1725-1807). The second son of James Edward Stuart, the Elder Pretender. See Stuart.

STUART, James. Regent of Scotland after the abdication of Queen Mary. See Murray or Moray, James Stuart, Earl of.

STUART, James (1713-88). An English painter, archæologist, and architect, born in London. Until nearly thirty years of age he was a poor fan-painter, but in 1741 he found means to go to Rome, where he studied Latin and Greek and became interested in archæology. From 1751 till 1755 he, together with Nicholas Revett, studied antiquities in Athens. Upon their return to England they published, through the encouragement and aid of the Society of Dilettanti, *The Antiquities of Athens, Measured and Delineated by James Stuart, F.R.S. and F.S.A., and Nicholas Revett, Painters and Architects* (1762). The book attracted widespread attention. Through its influence the classical style in architecture became widely popular. A second volume of the *Antiquities* was published posthumously in 1789; a third in 1795; and a fourth in 1814. A third edition of the first three volumes was published in 1841 for Bohn's *Illustrated Library.*

STUART, James Francis Edward (1688-1766). The son of James II. of England by his second wife, Mary Beatrice, daughter of the Duke of Modena, known as the Chevalier Saint George, or the Old Pretender. Prince James, who was born but a few months before his father's dethronement, was commonly but groundlessly alleged to be a supposititious child, and was involved in his father's exclusion from the crown. In 1715 the party who supported him, known in history as the Jacobites, endeavored to place him on the throne by force of arms. In Scotland the Earl of Mar, with about 5000 men, was checked by the royal forces under the Duke of Argyll at Sheriffmuir (q.v.), and in England the rising, headed by the Earl of Derwentwater, ended by the unconditional surrender of the insurgents at Preston, when Lords Derwentwater and Kenmure were beheaded and other persons of note executed and attainted. James escaped to France, and for the rest of his life resided in obscurity, principally at Rome. In 1719 he married one of the wealthiest heiresses in Europe, Maria Clementina Sobieski, granddaughter of John Sobieski, King of Poland. His son Charles Edward was the Young Pretender.

STUART, James Ewell Brown (1833-64). An American soldier, prominent as a cavalry leader in the Confederate service during the Civil War. He was born in Virginia, attended Emory and Henry College, and graduated at the United States Military Academy in 1854. He then served as lieutenant on the Texas frontier, taking part in several actions with the Apache Indians. In 1857 his regiment was sent to Kansas to maintain peace, and later he saw service against the Cheyenne Indians. In April, 1861, he was promoted to the rank of captain, but resigned from the United States Army upon receiving notice of the secession of Virginia, and was shortly thereafter commissioned lieutenant-colonel of Virginia troops. At the first battle of Bull Run he won distinction as a cavalry commander, and was rewarded in September following by promotion to the rank of brigadier-general. He made several successful raids and took a conspicuous part in the Seven Days' Battle before Richmond. In July, 1862, he was commissioned major-general of cavalry, and shortly afterwards made a dash upon General Pope's headquarters, capturing his official correspondence and making prisoners of several of his staff. This was followed the same night by a successful raid on Manassas Junction. He participated with distinction in the second battle of Bull Run and in the battle of Antietam, made a raid into Pennsylvania, guarded the Confederate right at Fredericksburg, and aided Stonewall Jackson at Chancellorsville. After the death of Jackson and the wounding of A. P. Hill, the command of Jackson's corps devolved temporarily upon him. He took part in Lee's Gettysburg campaign without adding anything to his reputation as a cavalry commander. In the campaign of the Wilderness he won several successes; and when Sheridan advanced upon Richmond General Stuart confronted him at Yellow Tavern, where the Confederates were defeated and General Stuart mortally wounded. He died May 12, 1864. Consult his *Life and Campaigns*, by H. B. McClellan, his chief of staff (Boston, 1885).

STUART, John. See Bute, third Earl of.

STUART, John McDouall (1815-66). A British explorer, born at Dysart, in Fifeshire. In 1838 he emigrated to South Australia. He was

with Captain Sturt on an expedition to explore Central Australia, and in 1858 began the work of exploration on his own account. In October, 1861, he started northward, and in July, 1862, arrived at Van Diemen's Gulf. For this exploit he received from South Australia the grant of £2000, which had been offered to the first colonist who should cross the continent.

STUART, Moses (1780-1852). An American scholar and teacher. He was born at Wilton, Conn., and graduated at Yale in 1799. After several years as a teacher he was admitted to the bar in 1802, but abandoned the law for theology. He was pastor of a church in New Haven (1806-09), but is best known for his service as professor of sacred literature at Andover Theological School (1810-48). He was an inspiring teacher, an indefatigable student, and one of the first to make German scholarship known in America. He prepared several Hebrew grammars, the first of which was used by his classes in manuscript because he was unable to find type or compositors to print it; the last was a translation of Rödiger's *Gesenius* (1846); with Edward Robinson he translated Winer's grammar of New Testament Greek (1825); he also translated writings of Jahn and others on methods of biblical study (1821), and Ernesti's *Elements of Interpretation* (1822).

STUART, Ruth McEnery (1856—). An American writer of stories dealing chiefly with Southern scenes. She was born in Avoyelles Parish, La., and was educated at New Orleans. Her chief publications are: *A Golden Wedding and Other Tales* (1893); *Carlotta's Intended* (1894); *The Story of Babette* (1894); *Solomon Crow's Christmas Pockets and Others* (1896); *Sonny* (1896); *In Simkinsville* (1897); *Moriah's Mourning* (1898); *Holly and Pizen* (1899); *The Woman's Exchange* (1899); *Napoleon Jackson* (1902).

STUBBES, stŭbz, Philip (c.1555-c.1610). A Puritan pamphleteer of the sixteenth century. In 1583 he wrote, in denunciation of the social follies and vices of the age, *The Anatomie of Abuses;* and in the same year he published *The Rosarie of Christian Praiers and Meditations.* He wrote also *A Christall Glasse for Christian Women* (1590), and numerous pamphlets. Both *The Anatomie of Abuses* and *A Christall Glasse* were very popular, and were several times republished. The former was reprinted in 1836 by Trumbull, and afterwards was edited in two parts with 'forewords' by Dr. Furnival, for the Shakespeare Society (1877, 1882). Consult volume ix. of Morley's *English Writers* (London, 1892).

STUBBS, Charles William (1845—). An English divine and author, born in Liverpool. From the Royal Institution School of Liverpool he passed to Sidney Sussex College, Cambridge, where he graduated B.A. in 1868. He became senior curate of Saint Mary's, Sheffield (1868-71), vicar of Granboro in Buckinghamshire (1871-84), of Stokenham in Devonshire (1884-88), rector of Wavertree, Liverpool (1888-94), and Dean of Ely (1894). Among his writings are: *Christ and Democracy* (1883); *God's Englishmen* (1887); *The Land and the Labourers* (1890); *Christ and Economics* (1893); *Christus Imperator* (1894); *A Creed for Christian Socialists* (1896); *Charles Kingsley and the Christian Social Movement* (1898); *The Social Teaching of the Lord's Prayer* (1900); *Pro Patria* (1900). He is also the author of two volumes of poems, *The Conscience* (1884) and *Brightnoth's Prayer* (1899).

STUBBS, George (1724-1806). An English animal painter and anatomist. He was born in Liverpool, where he began the study of his father's profession of surgery. In 1751, however, he went to Rome to study art. Upon his return to England he was soon receiving good prices for paintings of horses, and after 1758 devoted most of his time for six or seven years to the preparation of his famous *Anatomy of the Horse* (1766), a work which, from the standpoint both of anatomy and art, is still authoritative. In 1790 he was engaged to paint all the famous race-horses from the time of the Godolphin Barb, but he only completed 16 in the series. He did some notable work in enameling on large plates. Some of his rustic and heroic pieces were very popular as engravings, but his paintings of horses have never been surpassed for realism and accuracy. Among his best known pictures are "The Grosvenor Hunt," "Horse Affrighted by a Lion," "The Brick Cart," "Warren Hastings," and "Horse and Jockey." In 1900 he exhibited his largest picture, measuring more than 13 feet by 8, which represents "Hambletonian beating Diamond at Newmarket."

STUBBS, or **STUBBE,** John (c.1543-1591). A Puritan zealot, born in Norfolk, England. He was possessed of a fiery zeal against Catholicism, and was so opposed to the Queen's proposed marriage with the Duke of Anjou that, in 1579, he published a pamphlet entitled *The Discoverie of a gaping gulf wherein England is like to be Swallowed by Another French Marriage if the Lord Forbid not the Banes by Letting Her Majestie see the Sin and Punishment Thereof.* Though the pamphlet spoke of the Queen in respectful and loyal terms, Stubbs, his publisher, and the printer were found guilty on a charge of disseminating seditious writings and were sentenced to have their right hands cut off. This cruel punishment was, in fact, inflicted upon Stubbs and the publisher in the market-place at Westminster. When Stubbs's right hand was stricken off, he waved his hat with his left, and cried out, 'God save the Queen!' Nor did the treatment he had received ever lessen his fidelity to his sovereign.

STUBBS, William (1825-1901). An English historian and prelate. He was born at Knaresborough, in Yorkshire, and educated at Ripon Grammar School and at Christ Church, Oxford, being elected to a fellowship at Trinity in the year of his graduation (1848), and ordained in the same year. His *Registrum Sacrum Anglicanum,* a calendar of the English bishops from Saint Augustine (1858), attracted the attention of Archbishop Longley by the learning displayed in it, and won for him the appointment of librarian at Lambeth Palace. In 1866 he was appointed regius professor of modern history at Oxford, and during the eighteen years of his tenure of this chair he had an exceedingly wide influence on historical study in England. His great *Constitutional History of England* (1874-78) at once took rank as the standard authority on the subject, down to the times of the Tudors. He was appointed canon of Saint Paul's in 1879,

Bishop of Chester in 1884, and Bishop of Oxford in 1889. He died in London. His historical work was all of the careful modern type, based on faithful study of contemporary documents, many valuable specimens of which he edited. His *Historical Introductions to the Rolls Series* have now been rendered generally accessible by publication in one volume (ed. Hassall, London, 1903). Other notable works are: *Seventeen Lectures on the Study of Mediæval and Modern History* (1886; 3d ed. 1900); and *Councils and Ecclesiastical Documents Relating to Great Britain and Ireland*, edited with A. W. Haddan (1869-73). A volume of *Ordination Addresses* appeared after his death (1901). A complete list of his historical works may be found in Gross, *Sources and Literature of English History* (New York, 1900).

STUCCO (It., from OHG. *stucchi*, Ger. *Stück*, AS. *stycce*, piece, patch; connected with OHG. *stoc*, Ger. *Stock*, AS. *stocc*, Eng. *stock*, stake, club, Skt. *tuj*, to thrust). A composition used for the finer parts of plaster-work, such as cornices and enrichments. Gypsum (q.v.), or plaster of Paris, is used for this purpose. A coarser kind of stucco is also used for making floors, and for plastering the exterior of buildings. The Greeks used stucco to give a finer surface to their coarse stonework, even in their columns, before the finer marbles were used. The Romans also in the temples they built after the Greek manner in the late Republic stuccoed nearly all their exterior surfaces. This stucco was made partly of marble dust, was extremely fine and of a hard and brilliant finish, equal to marble. Stucco was also used for more artistic purposes in late classic art. While wet it was fashioned into ornamental or figured low reliefs. Ceilings and walls in baths (e.g. Pompeii and Roman thermæ), tombs (on the Via Latina), and private houses have preserved these decorations under the Empire, probably from Alexandrian models. Those found near the Farnesina in Rome and now in the Museo delle Terme are among the most charming decorative works of any period. Early Christian art continued the style, as is shown by the well-preserved internal decoration of the baptistery of the cathedral in Ravenna. It was not unknown to the Middle Ages, witness the angels in the church at Hildesheim, and it again became popular during the Renaissance, being profusely used in the ceilings of the later period, often with Rococo designs.

STUCK, stụk, FRANZ (1863—). A German painter and sculptor, one of the leaders of the so-called Secessionists (q.v.). Born at Tettenweis, Bavaria, he studied at the Munich Academy under Lindenschmit, and became first known through his drawings for the *Fliegende Blätter*, and the two series of art-industrial designs which appeared in Vienna under the titles *Allegorien und Embleme* and *Titel und Vignetten*, rugged rather than refined, but full of vitality and bold in treatment. His first paintings, "The Guardian of Paradise," "Innocentia," and "Fighting Fauns,' exhibited in Munich in 1889, were awarded the gold medal, initiating a series of artistic successes attendant upon his well-known landscapes enlivened with centaurs, fauns, and nymphs, and his impressive delineations of human passions, of which the figure of "Sin" (1893), Eve enfolded by a huge serpent, and, on a larger scale, the allegory of "War" (1894), both in the Pinakothek at Munich, have become particularly famous. In the meanwhile he had painted "Expulsion from Paradise," a "Pietà" (1892), and "Crucifixion" (1892, Stuttgart Museum), a startling deviation from the traditional treatment of this subject. A marked progress in the artist's power of expression was shown in "The Sphinx" (1895, National Museum, Budapest), "Evil Conscience" (1896), and "Procession of Bacchants" (1897). His plastic work, all small figures in bronze, exhibits the same powerful realism in the treatment of form as do his paintings. A characteristic example is the statuette of a "Faun" (National Gallery, Berlin; replicas Kunsthalle, Hamburg, and National Museum, Budapest). Consult the monographs by Bierbaum (Leipzig, 1899), Meissner (Berlin, 1899), and Weese (Vienna, 1903); also Schultze-Naumburg, in *Magazine of Art*, vol. xx. (London, 1896-97).

STÜCKELBERG, stụ'kel-bĕrk, ERNST (1831-1903). A Swiss genre and landscape painter, born in Basel. He studied under Dietler of that city, and in Antwerp, Paris, Munich, and Italy. In 1869 he won the gold medal at Munich. Among his pictures may be mentioned "A Procession in the Sabine Mountains" (1859, Basel), "The Children's Service" (1867), and "Charcoal Burners in the Swiss Mountains" (Zurich). In 1877 Stückelberg was commissioned to execute a large symbolic fresco, "The Awakening of Art," for the Gallery of Basel. He also won a competition, in the same year, for designs to fresco the Tell Chapel on the Lake of the Four Cantons. The work was completed in 1887.

STUCKENBERG, stụk'en-bĕrg, JOHN HENRY WILBURN (1835-1903). An American Lutheran clergyman and author, born at Bramsche, Hanover. He emigrated to America with his parents when a very young man and settled in the West, was graduated from Wittenberg College, Ohio, in 1857, and studied in the universities of Halle, Göttingen, Berlin, and Tübingen. Coming back to America, he was ordained a Lutheran minister and held pastoral charges in Pennsylvania and Iowa. In 1873 he was made professor of theology in Wittenberg College, but in 1880 went to Germany again, where he became pastor of the American Chapel in Berlin. After many years in this service he returned to America and took up his residence in Cambridge, Mass. His later years were largely devoted to the study of theoretical sociology, to which he made valuable contributions. His chief works are: *History of the Augsburg Confession* (1869); *Christian Sociology* (1880); *Life of Immanuel Kant* (1882); and *Sociology* (1903).

STUCLEY, stūk'lĭ, or **STUKELY**, THOMAS (c.1525-78). An English adventurer. He was the third son of Sir Hugh Stucley of Devonshire. About 1552 he went to France, and there gained the favor of the King, Henry II., who sent him to England to obtain information to be used in a projected attack on Calais. Stucley, however, revealed the nature of his mission to the English Government, but, instead of being rewarded, was imprisoned in the Tower. In 1563, with the patronage of Queen Elizabeth, he pretended to join Ribault's colonization expedition to Florida, but instead turned privateer, and seized many French, Spanish, and Portuguese vessels. After

two years of this life he was seized at Cork, but apparently was not brought to trial. For several years afterwards he was employed in Ireland, but, having intrigued with Spanish agents, he ultimately fled to Spain. In 1571 Stucley commanded three vessels at the battle of Lepanto, and seven years later, while in the service of Sebastian of Portugal, was killed in the battle of Alcazar in Morocco. He became the hero of numerous ballads and plays. One of these, *The Famous History of the Life and Death of Captain Thomas Stukely*, was printed "as it hath been acted," in London in 1605. It was reprinted in Simpson's *School of Shakespeare* (1878), with a biography of Stucley prefixed.

STUD-BOOK. A genealogical record of blooded stock. The British Stud-Book for horses is the oldest in existence and was first commenced in 1791. All the facts that are in existence regarding the evolution through systematic breeding of the modern horse is obtained through the British Stud-Book. There are similar records for cattle and dogs.

STUDER, stōō'der, BERNHARD (1794-1887). A Swiss geologist, born at Büren, Canton of Bern. He studied at Bern, Göttingen, and Paris, and in 1825 was made professor of geology in Bern, where he labored continuously until 1873. Some of the more important of his works are: *Beiträge zu einer Monographie der Molasse* (1825); *Geologie der westlichen Schweizeralpen* (1834); *Lehrbuch der physikalischen Geographie und Geologie* (1844-47); *Geologie der Schweiz* (1851-53); and *Zur Geologie der Berner Alpen* (1866).

STUHLMANN, stōōl'män, FRANZ (1863—). A German zoölogist and African explorer, born in Hamburg. After studying at Tübingen and Freiburg, he went to East Africa in 1888, and during the revolt of the Arabs in 1890 entered the German corps of defense as a lieutenant, and was severely wounded at Mlembule. After his recovery he joined the expedition of Emin Pasha to the lake region, was sent ahead from Undussuma to Lake Victoria, and reached the coast in July, 1892, at Bagamoyo, whence he returned to Germany with valuable cartographic material and rich collections, to which he added copiously on another trip to German East Africa, undertaken in 1893-94 by order of the Government. He published *Zoologische Ergebnisse einer in die Küstengebiete von Ostafrika unternommenen Reise 1888-90* (1893-1901), and *Mit Emin Pascha ins Herz von Afrika* (1894).

STUHLWEISSENBURG, stōōl'vī'sen-bōōrk (Hung. *Székes-Fehérvár*). A royal free city, capital of the county of the same name, Hungary, 35 miles southwest of Budapest (Map: Hungary, F 3). The episcopal palace and the cathedral are noteworthy edifices. The manufactures of woolens, silks, and knives are extensive and the agricultural interests prominent. Stuhlweissenburg is the Alba Regia of the Romans. From the eleventh to the sixteenth century the kings of Hungary were crowned there; afterwards the ceremonial took place at Pressburg. The city was held by the Turks from 1543 to 1688, with the exception of the period 1601-02. Population, in 1890, 28,942; in 1900, 32,167.

STUKELY, stūk'lī, WILLIAM (1687-1765). An English antiquary, born at Holbeach, Lincolnshire. He graduated at Bennet (Corpus Christi) College, Cambridge, in 1708. With Roger Gales he made long antiquarian tours in various parts of England. Among his many published works are: *An Account of a Roman Temple and Other Antiquities, near Graham's Dike in Scotland* (1720); *Itinerarium Curiosum* (1724, 2d ed. 1776); *Stonehenge* (1740); *Abury, a Temple of the British Druids* (1743); *Palæographia Britannica* (1743-52); and *The Medallic History of M. A. V. Caurasius* (1757-59).

STÜLER, stü'lēr, FRIEDRICH AUGUST (1800-65). A German architect, born in Mühlhausen, Thuringia. He studied first in Berlin and afterwards in France and Italy. Appointed Court inspector of buildings at Berlin in 1830, he was two years later put at the head of the architectural commission of the royal palace. His principal buildings include the New Museum (1843-55), the churches of Saint Bartholomew (1854-58), Saint James (1845), Saint Mark (1848-55), and Saint Matthew (1846), as well as parts of the royal palace in Berlin, the Academy of Sciences at Budapest, the National Museum of Stockholm (1850-66), the Museum at Cologne (1855-61), the reconstructed Winter Palace at Saint Petersburg, the University at Königsberg (1844-63), and the reconstruction of the Stolzenfels Castle and the Hohenzollern Castle (1850-67).

STUMM, stum, KARL FERDINAND, Baron von Halberg (1836-1901). A German manufacturer and politician, born in Saarbrücken. He studied in Bonn and Berlin, and in 1858 became the head of the family firm which had for many years owned the great iron works at Neunkirchen. He was a member of the Prussian Chamber from 1867 till 1870, and of the Reichstag from 1867 till 1881, and from 1889 till his death in 1901; and was one of the founders of the German Reichspartei. Over his thousands of workmen he exercised a sort of paternalistic rule, and he furnished them with hospitals, technical schools, a library, model dwellings, and many other advantages. He was bitterly hostile to socialism.

STUMPF, stumpf, KARL (1848—). A German psychologist, born at Wiesentheid, Bavaria. He studied at Würzburg and Göttingen, being especially influenced by the teachings of F. Brentano and R. H. Lotze. After qualifying as privat-docent at Göttingen, in 1870, he was appointed to the chair of philosophy successively at Würzburg (1873), Prague (1879), Halle (1884), Munich (1889), and Berlin (1894), where he instituted the psychological seminar. In 1895 he became a member of the Prussian Academy of Sciences. His publications include numerous monographs upon psychology, æsthetics, ethnology, epistemology, and especially upon physical and psychological acoustics. They comprise: *Ueber den psychologischen Ursprung der Raumvorstellung* (1873); *Tonpsychologie* (1883-90); *Tafeln zur Geschichte der Philosophie* (2d ed. 1900); *Psychologie und Erkenntnistheorie* (1891); *Beiträge zur Akustik und Musikwissenschaft, I. Consonanz und Dissonanz* (1898). He is best known by his contributions to the psychological study of sensations of tone and their use in music.

STUNDISTS (from Ger. *Stunde*, hour lesson; so called from their meetings to read the

Bible). A Russian sect, which owes its origin to German influences. It has gained many converts among the peasants, particularly since 1870, and has attracted the hostile attention of the Government. The Stundists bear some resemblance to the Anabaptists, give to the sacrament a purely symbolic interpretation, and hold communistic views concerning property. They are most numerous in Little Russia and Bessarabia.

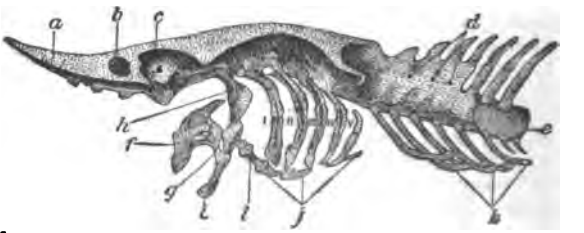
STUPA. A form of Buddhist architecture in India. See TOPE.

STURDY. A disease of sheep. See GID.

STURDZA, stōōrd'zȧ, ALEXANDER (1791-1854). A Moldavian publicist and diplomat, educated in Germany and afterwards in the service of Russia. His *Mémoire sur l'état actuel de l'Allemagne,* published at the Congress of Aix-la-Chapelle in 1818, by order of Alexander I., aroused great indignation in Germany because of the unbecoming levity with which its author arraigned the German national character and branded the universities as hotbeds of the revolutionary spirit and atheism. In 1819 he settled at Dresden, married a daughter of Hufeland, and subsequently retired to his estate of Mansyr, Bessarabia. Of his other writings may be mentioned *La Grèce en 1821* (1822); a biography of Hufeland (1837); and *Œuvres posthumes religieuses, historiques, philosophiques et littéraires* (1858-61).

STURDZA, DEMETER (1833—). A Rumanian statesman and author. He studied political science at Munich, Göttingen, Bonn, and Berlin, became Minister of Public Instruction in 1859, and was one of the most zealous promoters of the overthrow of Cuza and the election of Prince Charles of Hohenzollern, in 1866. In the Cabinet of Bratianu, 1876-88, he held repeatedly ministerial posts, and in 1895-96 presided over a National-Liberal Ministry. Again in 1897-99 and since 1901 he was at the head of the Government as president of the Council and Minister of Foreign Affairs. He wrote *La Marche progressive de la Russie sur le Danube* (1878); *Uebersicht der Münzen und Medaillen des Fürstentums Rumänien* (1874); *Europa, Russia, Romania* (1888); *La question des portes de fer et des cataractes du Danube* (1899); and *Charles I., roi de Roumanie* (1899 et seq.).

STURE, stōō're. A noble family of Sweden which played a very prominent part in the affairs of that country in the fifteenth and sixteenth centuries and became extinct in 1616. Its chief representatives were: (1) STEN STURE the Elder (d.1503). He was a son of Gustaf Sture and the nephew of King Charles VIII., on whose death, in 1470, he became Regent of Sweden, in spite of the opposition of the Swedish nobility, who supported the claims of Christian I. of Denmark. He defeated the Danish King in the battle of Brukeberg, near Stockholm (1471). He introduced printing, and founded the University of Upsala (1477). In 1497 he was forced to resign his place to John of Denmark, but regained power in 1501 and ruled till his death (1503). He was followed by (2) SWANTE NILLSON STURE, a kinsman, who also kept the Danes and the nobility in check and died in 1512. (3) The latter's son, STEN STURE the Younger, aided by the peasantry, foiled the plan of the nobles to place Trolle, one of their own number, in power, gained the Regency for himself, twice defeated (1517 and 1518) Gustaf Sture, Archbishop of Upsala, whom he had deposed in 1517, and was himself defeated and mortally wounded in a battle against Christian II. of Denmark at Bogesund in 1520. His widow, Christina Gyllenstierna, held Stockholm until the new King guaranteed a constitutional government. (4) His son, SWANTE STURE, though a loyal partisan of the House of Vasa, was murdered by Eric XIV. (1567).



STURGEON (AF. *sturjoun,* OF., Fr. *esturgeon,* Sp. *esturion,* It. *storione,* from ML. *sturgio, sturio,* from OHG. *sturjo, sturo,* Ger. *Stör,* AS. *styria, stiriga,* sturgeon; perhaps connected with OHG. *stōran,* Ger. *stören,* AS. *styrian,* Eng. *stir*). A large fresh-water fish of the ganoid family Acipenseridæ. Sturgeons have an elongated, subcylindrical body, armed with five rows of bony plates or bucklers, each bearing a median keel. The head is covered by bony plates joined by sutures. The snout is produced; the mouth is inferior, opening on the under side of the head,

A FOSSIL STURGEON.

A long-beaked sturgeon (*Belonorhynchus striolatus*) fossil in the Trias and Lias formations of the Old World.

protractile and without teeth. Just anterior to the mouth there are four barbels. The tail has the upper lobe much larger than the lower. There is a single dorsal fin, placed like the anal fin far back. They have a large air bladder, connected by a tube with the œsophagus. About 25 species, in two genera, are recognized, all inhabitants of the fresh waters and seas of the northern regions. Most of the species are migratory and ascend streams to spawn, but some live permanently in fresh waters. They spawn in the spring and summer, and are very prolific, a large female producing from two to three million eggs, constituting from a fifth to a third of its

a, Rostrum; *b,* nasal capsule; *c,* eye-socket; *d,* foramina for spinal nerves; *e,* notochord; *g,* quadrate bone; *h,* hyomandibular bone; *i,* mandible; *j,* basibranchials; *k,* ribs; *l,* hyoid bone; I, II, III, IV, V, branchial arches.

entire weight. They feed on small animals and plants, which they suck into their mouth. The common sturgeon (*Acipenser sturio*), of the coasts and rivers of Europe and Northeastern America, has been known to weigh 500 pounds. The lake or rock sturgeon (*Acipenser rubicundus*), once very abundant in the Great Lakes and the Mississippi Valley, attains a weight of 200 pounds,

STURGEONS, PADDLE-FISH, AND BOWFIN

1. SHOVEL-NOSED STURGEON (Scaphirhynchus platyrhynchus).
2. PADDLE-FISH (Polyodon spathula), side view.
3. PADDLE-FISH, ventral view.
4. LAKE STURGEON (Acipenser rubicundus).
5. COMMON STURGEON (Acipenser sturio).
6. BOWFIN (Amia calva); in proportion to the other figures much enlarged.

but the average is much less. Its sides are reddish, often with irregular blackish spots. Very peculiar in its prolonged paddle-shaped snout is the 'shovelnose' or 'white' sturgeon (*Scaphirhynchus platyrhynchus*), which is pale olive in color and about five feet long. It is a denizen of the Western and Southern States. Similar species occur in Asia. The largest of American sturgeons is that of the Pacific Coast (*Acipenser transmontanus*) called 'white' in comparison with the rare 'green' sturgeon (*Acipenser medirostris*). The former weighs 300 to 600 pounds, and is used as food, but the latter, which is nearly as large, but olive green, is not eaten. A giant beside these is the great Russian 'bielaga' or 'huso' (*Acipenser huso*), which has been known to attain a length of 20 to 25 feet and a weight of 3000 pounds. It is this species, once extremely abundant in the Danube, Volga, and other large rivers emptying into the Black and Caspian seas, which has furnished mainly the salted roe called caviar (q.v.), though some comes from the diminutive sterlet (*Acipenser ruthenus*) of the same region. The air bladder is also utilized for making isinglass.

Fossil sturgeon remains indistinguishable from the corresponding portions of the skeletons of modern species have been found in rocks as old as the Eocene. Earlier less specialized ancestral forms are Chondrosteus of the Jurassic and perhaps also the still older Palæoniscus of the Permian and Cheirolepis of the Upper Devonian. See CHIROLEPIS; CHONDROSTEUS; PALÆONISCUS.

Consult authorities cited under FISH and FISHERIES; and see Plate of STURGEONS.

STURGEON, stûr'jŭn, WILLIAM (1783-1850). An English electrician, born at Whittington, in Lancashire. As early as 1823 he constructed a soft-iron electro-magnet, and in 1830 described for the first time the process of amalgamating the zinc plate of a battery with mercury. In 1832 he constructed an electro-magnetic rotary engine, the first contrivance by means of which any considerable mechanical force was developed by the electric current; and he shares the honor of this invention with Oersted. Five years afterwards he produced an electro-magnetic coil for giving shocks. About the same time he ascertained by means of kites that in fair weather the atmosphere is positive with regard to the earth. Later he devised and constructed the commutator, now in universal use. Among his works are: *Experimental Researches in Electro-Magnetism, Galvanism, etc.* (1830); *Lectures on Electricity Delivered in the Royal Victoria Gallery, Manchester* (1842); *Twelve Lectures on Galvanism* (1843); and *Scientific Researches* (1850).

STURGEON BAY. The county-seat of Door County, Wis., 45 miles northeast of the city of Green Bay, on a canal connecting Green Bay and Lake Michigan, and on the Ahnapee and Western Railroad (Map: Wisconsin, F 4). It has considerable industrial importance. There are canning establishments, ship yards, and manufactories of lumber, beer, flour, foundry and machine-shop products, etc. Population, in 1890, 2195; in 1900, 3372.

STURGIS, RUSSELL (1836—). An American architect and author, born in Baltimore, Md. He studied architecture in New York and in Europe, and practiced his profession from 1865 till 1880. In that time he designed Battell Chapel, Farnam Hall, Durfee Hall, and Lawrence Hall of Yale College; the Homœopathic Medical College and Flower Hospital in New York, and many other buildings in various parts of the country. In 1878 he became professor of architecture and the arts of design in the College of the City of New York, but resigned in 1880 on account of ill health, and went abroad for five years. After 1885 he was editor of decorative art and mediæval archæology of the *Century Dictionary;* editor of fine arts of *Webster's International Dictionary;* and editor of archæology and fine arts of *Johnson's* (now Appleton's) *Universal Cyclopædia* (ed. of 1893-95). In January, 1898, he began editing the "Field of Art," a department in *Scribner's Magazine.* His published works include: *Manual of the Jarves Collection of Early Italian Pictures* (1868); *European Architecture: An Historical Study* (1895); *Annotated Bibliography of Fine Art* (1897); and *How to Judge Architecture* (1903). He contributed articles on art subjects to the *New International Encyclopædia,* and he was the editor and chief author of the *Dictionary of Architecture and Building* (1901-02).

STURGIS, SAMUEL DAVIS (1822-89). An American soldier, born at Shippensburg, Pa. He graduated at West Point in 1846, served through the Mexican War, and was taken prisoner during the operations before Buena Vista. At the outbreak of the Civil War he was obliged to abandon Fort Smith, Ark., of which he was commandant, but succeeded in saving his command. As major of the Fourth Cavalry he served in 1861 under General Lyon, and succeeded to his command at Wilson's Creek (q.v.). He was prominent at South Mountain, Antietam, Fredericksburg, and had command of the cavalry of the Department of the Ohio in 1863-64, in January of the latter year capturing General Vance and his command and routing General Martin's Confederate cavalry. Later he took an important part in an expedition against General Forrest. In 1869 he was promoted to be colonel of the Seventh Cavalry. From 1881 to 1885 he was governor of the Soldier's Home near Washington, and the next year he retired from active service.

STURLUSON, SNORRI. See SNORRI STURLUSON.

STURM, stŭrm, JACQUES CHARLES FRANÇOIS (1803-55). A French mathematician, born at Geneva. He was educated at the Academy of Geneva, and in 1827, with his friend Colladou, took the *Grand prix de mathématiques* for the best memoir on the compression of liquids. The famous theorem that bears his name was discovered in 1829. A statement of the results secured by this theorem requires the definition of Sturm's functions: If $f(x) = 0$ be freed from equal roots, and $f(x)$ be divided by $f'(x)$ (the derivative of $f(x)$), and the last divisor by the last remainder, changing the sign of each remainder before dividing by it, until a remainder independent of x is obtained, or else a remainder which cannot change its sign, then $f(x)$, $f'(x)$, and the successive remainders, constitute Sturm's functions. The theorem asserts that if, as x increases, $f(x)$ passes through the value zero, Sturm's functions lose one change of sign; if any other of Sturm's functions vanishes, there is neither

loss nor gain in the number of changes of sign; the number of roots of $f(x)=0$ between a and b is equal to the difference in the number of changes of sign in Sturm's functions, when $x=a$ and when $x=b$. In 1838 Sturm began teaching in the Ecole Polytechnique, and two years later was elected to the chair made vacant by the death of Poisson.

STURM, or **STURMIUS**, JOHANNES (1507-89). A prominent educator of the sixteenth century. He was born near Cologne, and was educated at Leyden and Louvain. In 1537, at the instance of the magistrates of Strassburg, he organized the Strassburg Gymnasium, which he directed for forty-three years. He was relieved from his position in 1581 on account of religious disputes and differences. Through his system of gradation of classes, practically the same that still prevails in all German gymnasia, the classification of literary material for use in schools, the writing of text-books, and the organization of school management, he shaped the practice of secondary education not only in the German schools, but also in the great secondary schools of England and France.

STURM, stōōrm, JULIUS (1816-96). A German poet, born at Köstritz, Reuss. After studying theology at Jena (1837-41), he was private tutor to the hereditary prince Henry XIV. of Reuss, then pastor at Göschitz, near Schleiz, in 1851-57, and at Köstritz from 1857 to 1885. He died at Leipzig. All his lyrics reveal him as a poet of deep religious sentiment and genuine national spirit. The religious poems are incorporated in the collections *Fromme Lieder*, three parts (1852, 1858, 1892); *Zwei Rosen oder das Hohe Lied der Liebe* (1854); *Von der Pilgerfahrt* (1868); *Gott grüsse dich* (1876); *Dem Herrn mein Lied* (1884); *Palmen und Krone* (1888); and others; while the volumes with secular contents include: *Für das Haus* (1861); *Lieder und Bilder* (1870); *Kampf- und Siegesgedichte* (1870); *Spiegel der Zeit in Fabeln* (1872); *Kinderleben* (1877), illustrated by Ludwig Richter; *Immergrün* (1880); *Natur, Liebe, Vaterland* (1884); *In Freud und Leid* (1896). For his biography consult Hepding (Giessen, 1896) and Hoffmann (Hamburg, 1898).—His son AUGUST (1852—), born at Göschitz, also won reputation as a poet. He studied at Jena, Leipzig, and Berlin, first theology, afterwards law, which he practiced at Naumburg, since 1884, having in the meanwhile lived as assessor at Rudolstadt (1880-82) and, given to literary pursuits, in Berlin (1882-84). Besides the epic poems, *Merlin* (1892), *Kaiser Friedrich der Edle* (1896), *König Laurins Rosengarten* (1897), and *Der König von Babel* (1902), he published *Hohenzollernsagen, Balladen* (1898); the lyrics *Auf Flügeln des Gesanges* (1883); *Lied und Leben* (1889); *Auf der Höhe* (1902); and others; several dramas and the sketches in prose, *Sylter Skizzen* (1887); also a series of juridical works, notably *Revision der gemeinrechtlichen Lehre vom Gewohnheitsrecht* (1900).

STURT, Sir CHARLES (1806-69). An Australian explorer. He was born in Bengal, India, of English parents; was educated in England; entered the British Army; and in 1825 went to New South Wales. In 1828 he headed an exploring expedition which penetrated the interior of Australia and discovered the Macquarie, Castlereagh, and Darling rivers, and in 1830 the Murray River, which he descended to Lake Alexandrina. Another expedition in 1844 reached the desert in the centre of the continent. He subsequently held high colonial positions. He became totally blind as a result of the hardships he had undergone, and returned to England in 1853; he was knighted shortly before his death. He published *Two Expeditions into the Interior of Southern Australia, 1828-31* (2 vols., 1833), and *Narrative of an Expedition into Central Australia in 1844* (2 vols., 1849).

STURZ, stōōrtz, HELFERICH PETER (1736-79). A German author, born at Darmstadt. He studied law (1753-58) at Jena, Giessen, and Göttingen, was appointed secretary in the department of foreign affairs at Copenhagen in 1764, soon after private secretary to Count Bernstorff, and in 1768 accompanied King Christian VII. to England and France. Involved in Struensee's downfall in 1772, he was imprisoned and banished from Copenhagen, but appointed again to a position at Oldenburg in 1773, and died at Bremen. His title to the reputation as one of the most tasteful German prose writers is amply demonstrated by the exquisite *Briefe eines Reisenden* (1777), and his *Erinnerungen aus dem Leben des Grafen von Bernstorff*. Consult the biography by Max Koch (Munich, 1879).

STUTTERING. Imperfect action of the organs of articulation resulting in defective speech. See STAMMERING.

STUTTGART, stut'gärt. The capital of the Kingdom of Württemberg, Germany, situated at an elevation of 890 feet, about 2 miles south of the Neckar, and 45 miles north of Tübingen (Map: Germany, C 4). Stuttgart occupies a delightful site surrounded by attractive suburbs and amid lovely vine-clad heights. The pronounced adherence of its many fine architects to the Renaissance types explains the stately appearance of the city.

The spacious Königstrasse extends diagonally from southwest to northeast through the old or inner city and borders the majestic Schlossplatz—the centre of interest. Here rises the impressive King William column (93 feet) embellished with allegorical figures. Here too are the splendid Königsbau, the palace of the Crown Prince, the Residenz-Schloss (palace), the royal theatre, and the royal stables. The fine statue of Schiller by Thorwaldsen, erected in 1839 by national subscription, is near by. Adjacent also is the striking Gothic Stiftskirche, begun in 1436. Southeast of the Old Palace is the palace of King William II., where the fine modern Neckarstrasse begins its course northeastward. In the immediate vicinity are housed the Württemberg archives and also the extensive and valuable natural history collections of Stuttgart. The royal public library near at hand contains upward of 500,000 volumes, 4000 manuscripts, and many specimens of early printing. The library building holds also the museum of Württemberg antiquities, among which may be seen ceramics, weapons, and articles taken from ancient tumuli and lake dwellings. In the rear of the library is the large modern Palace of Justice. Between the library and the Residenz-Schloss stands a spacious and famous academy —the Karlsschule. Extending northeast from

this vicinity and along the Neckarstrasse is the beautiful Schlossgarten. It embraces 200 acres, is 2 miles long, and is embellished with ponds, flower designs, and sculptures. Here are found the botanic garden, the mint, and the notable Stuttgart museum of art with its collections of sculpture and painting. In the northwest section of the city stands the Polytechnic Institute (over 1000 pupils) building facing the delightful Stadtgarten—one of the popular resorts. In the eastern part of Stuttgart is the immense new Liederhalle. In the vicinity of the Schlossplatz is found the modern Renaissance edifice of the Landesgewerbe Museum.

Among the prominent new buildings in Stuttgart are the Queen. Olga buildings, the new Town Hall, the Catholic Church of Saint Nicholas, and the Peace Church. The Uhlandshöhe and the Jägerhaus may be especially noted among the delightful resorts in the environs, as well as the royal country seat Wilhelma—a fine Moorish structure begun in 1842. Stuttgart has an art academy, the Württemberg Art Union with a permanent exposition of modern masters, an architectural school, an exposition of export products, the provincial industrial museum, a famous conservatory of music, an industrial and commercial library, and a chemical laboratory. It is the leading printing and book-publishing city of Southern Germany. Among its prominent manufactures are furniture, carriages, pianos, paper, leather, chemicals, colors, jewelry, bells, cigars, portmanteaus, chocolate, and especially cottons. Hops, cloth, and horses form special items in the trade. The city—the seat of all the important administrative offices of the kingdom—is under the general supervision of the royal Government. There are an over-burgomaster, two advisers, and a council of some 24 members. The population, in 1900, was 176,699, mainly Protestants.

HISTORY. Stuttgart is first mentioned in 1229. It became the official capital of Württemberg in 1482; but it did not begin to improve and assume its present splendid proportions until about 1800. Consult: Klaiber, "Stuttgart," in *Europäische Wanderbilder* (Zurich, 1892); Widmann, *Wanderung durch Stuttgart und Umgebung* (Stuttgart, 1896).

STUYVESANT, stī'vę-sant, PETER (1592-1672). A Dutch Governor of New York. He was born in Holland; early entered the military service of the Dutch in the West Indies, and in 1634 was made Director of the Colony of Curaçao. In 1646 the Dutch West India Company appointed him Director-General of their colony in North America, New Netherland, where he soon gained the confidence of the colonists by his efficient administration and public improvements. He reconciled the Indian tribes who had been made hostile by former unjust treatment, and succeeded in arranging with the New England commissioners, in 1650, the boundaries between the English and Dutch territories, but this was not entirely satisfactory to the Dutch colonists, who claimed that the Governor had ceded considerable territory to which they were rightfully entitled. A convention of delegated colonists in 1653 demanded for the people, among other things, a share in the appointment of local officers, but Stuyvesant ordered them to disperse forthwith, claiming that his authority was not from the people, but from God and the Dutch West India Company. The protracted contentions of the Dutch and the Swedes dwelling near the Delaware River about governmental jurisdiction became more critical in 1654, when the Swedish Governor seized the fort built by the Dutch where Newcastle now stands. To end this trouble, Stuyvesant in 1655 with 600 men sailed up the Delaware, recaptured the fort, and established the Dutch authority over the entire territory. After nine years of undisturbed quiet, in 1664 a force of English soldiers arrived under Colonel Nicolls, who demanded a surrender of the Government, on the ground that the whole territory had been given by royal charter to the Duke of York. The town at the time contained 1500 inhabitants and was defended by a stone fort and twenty cannon. Stuyvesant at first refused, but finding the people anxious to exchange rulers, he yielded to the English demand. Stuyvesant, in 1665, reported personally to the authorities in Holland, but soon returned to New York, where he spent the remainder of his life, cultivating an extensive farm called the Bouwerij (Bowery). He was buried where Saint Mark's Church now stands, and the elaborately inscribed stone that covered his grave is built into the eastern wall of the church. Consult the brief biography by Tuckerman (New York, 1893); and O'Callaghan, *The History of New Netherland* (ib., 1848).

STYE, or **STY** (formerly also *stian*, from AS. *stīgend*, stye, pres. part. of *stīgan*, Goth. *steigan*, OHG. *stīgan*, Ger. *steigen*, to rise; connected with OIr. *tiágaim*, I go, Lat. *ve-stigium*, footprint, Lett. *stiga*, path, OChurch Slav. *stignanti*, to hasten, Gk. *στείχειν*, *steichein*, to go). The popular name for an acute inflammation occurring around the follicle of an eyelash. It generally goes on to suppuration. It is known to surgeons under the term *hordeolum*. It begins as a small, red, tense swelling, accompanied with considerable itching and a feeling of stiffness. As the inflammation goes on, the lid may become so swollen as to keep the eye closed. In a few days pus forms; a yellowish point appears at the apex of the swelling; and when the cuticle gives way, pus and a small slough of connective tissue escape, after which there is a general remission of the symptoms, and the eyelid soon resumes its natural state.

The treatment includes the use of cold compresses to abort the stye, hot ones to hasten suppuration, and evacuation of pus when it appears. Errors of refraction should be corrected and the general health improved in order to prevent recurrence. The stye should never be rubbed (notwithstanding the common prejudice in favor of rubbing it with a gold ring).

STYLITE. See PILLAR SAINT.

STYLOBATE (Lat. *stylobata*, *stylobates*, from Gk. *στυλοβάτης*, base of a pillar, from *στῦλος*, *stylos*, pillar + *βαίνειν*, *bainein*, to go). The topmost step of the crepidoma (*κρηπίδωμα*) or substructure of a Greek temple. This consists of the foundations, or stereobate, and the surrounding steps, usually three in number. On the topmost step, the true stylobate, rest the columns. The term is sometimes extended to apply to the whole series of steps.

STYLONURUS (Neo-Lat., from Gk. *στῦλον*, *stylon*, acc. of *στῦλος*, *stylos*, pillar + *οὐρά*,

cave, tail). A gigantic extinct arthropod, allied to Eurypterus, with a body about 6 feet in length and with five pairs of legs, of which the posterior pair is much elongated, and a long spine on the tail. It is found in the Silurian and Devonian of Scotland and in the Upper Devonian of New York and Pennsylvania. Consult Beecher, "Restoration of Stylonurus lacoanus, a Giant Arthroped from the Upper Devonian of the United States," *American Journal of Science*, 4th series, vol. x. (New Haven, 1900). See ARTHROPODA; EURYPTERUS; MEROSTOMATA.

STYPTIC. An agent employed in surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See BLEEDING.

STYRAX. See STORAX.

STYRIA, stĭr'ĭ-ȧ (Ger. *Steiermark*). A duchy and crownland of Austria, bounded by Lower and Upper Austria on the north, Hungary on the east, Carniola and Carinthia on the south, and Carinthia and Salzburg on the west (Map: Austria, D 3). Its area is 8670 square miles. Styria is very mountainous. Its northern part belongs to the region of the central Alps, of which Styria takes in the Niedere Tauern, Rottenmanner Tauern, Dachstein, Totes Gebirge, and the Erzberg, the last named famous for its abundance of iron. The southern part is occupied by the Styrian Alps. The plains are generally small, but there are a large number of fruitful valleys along the Mur, Enns, and other rivers. Styria is watered chiefly by the Enns, Mur, Drave, and Save. There are many mountain lakes and mineral springs. Styria has a large proportion of productive land; the forests cover nearly one-half of the surface. Wheat, rye, corn, oats, and barley are the principal cereals. Hay is grown in large quantities, and cattle-raising is very important, especially in Upper Styria. Grapes and fruits are cultivated to a lesser extent. In mineral production Styria is one of the most important crownlands of Austria. In the output of lignite it ranks next to Bohemia, while in regard to iron it occupies the first place, supplying about 60 per cent. of the total output of Austria. It has also lead, zinc, sulphur, graphite, salt, and a great variety of useful earths and stones. The value of the mineral output of 1899 was about $5,000,000. The manufacturing industries are chiefly connected with the mineral products. There are large mills for the production of rails, sheet iron, wire, and smaller iron and steel articles. There are also several extensive machine shops, glass-works, distilleries, breweries, tobacco factories, and paper mills. The principal domestic exports are fruits, timber, cattle, and metal products. The Diet of Styria is composed of 60 members, of whom 12 represent the landed aristocracy, 19 the towns and industrial centres, 23 the rural communities, and 6 the chambers of commerce and trades of Gratz and Leoben. In the Lower House of Austria Styria is represented by 27 delegates. In 1898 Styria had 903 public schools, attended by 182,000 children, or 95 per cent. of the total school population. The population was 1,282,708 in 1890, and 1,356,058 in 1900. About 68 per cent. are Germans and the remainder Slovenians. The population is Roman Catholic. Capital, Gratz (q.v.).

HISTORY. Under Roman control the territory of Styria formed a portion of both Pannonia and Noricum, and was even then famous for its iron and steel. During the period of the great migration of nations the various invaders of the Italian peninsula swept through or settled in this district and at the close its population was essentially Slavic. It was a portion of the empire of Charles the Great, and was later included in the Carinthian mark erected against the Hungarians. Soon after the middle of the eleventh century the Margrave Ottokar styled himself Margrave of Steier, whence the region came to be known as Steiermark (Styria). In 1192 the region that is now the Duchy of Styria became a portion of the possessions of the dukes of Austria, and after belonging for a time to Ottokar II. of Bohemia, passed in 1276 into the possession of the Hapsburgs. The Reformation was welcomed by the people, but the intolerance of the Austrian rulers drove many of the inhabitants into exile.

STYX (Lat., from Gk. Στύξ, from στυγεῖν, *stygein*, to hate, loathe). In Greek legend, one of the rivers of the lower world. Probably originally the only stream which separated the region of the dead from the living. It was said that one-tenth of Oceanus streamed down to form the Styx, while the other nine-tenths surrounded the earth. As the goddess of this stream, Styx was the eldest daughter of Oceanus, and by the Titan Pallas mother of Zelos, Nike, Cratos, and Bia (Emulation, Victory, Might, and Force), with whom she joined Zeus at the beginning of the struggle with the Titans. For this she was made the guardian of the sacred oaths which bound the gods. She was described as living in the far west, in a house with silver pillars, where the water streamed from above. Thence Iris brought the water by which the gods swore, and terrible suffering awaited the divinity who committed perjury. With the development of the conceptions of the lower world, the rivers received various names, and Charon was introduced as the ferryman of souls across the Styx. The name was also given to a waterfall in northeastern Arcadia near Nonacris. The water descends over a cliff some 600 feet high on the side of Mount Chelmos into a wild and rugged glen, and the surroundings suggested to the Greeks the gloomy entrance to the lower world.

SUABIA. See SWABIA.

SUAHELI, swȧ-hē'lĭ. A people of Africa. See SWAHILI.

SUAKIM, swä'kĭm, or **SUAKIN.** A seaport of Egyptian Sudan, on a small island in the Red Sea in about latitude 19° N., and longitude 37° E. (Map: Africa, H 3). It is connected with the desert mainland by a railroad bridge. The town consists of two main parts. The Government buildings and the residences of the official class in the one section present an imposing appearance in direct contrast to the wretched dwellings of the natives in the other section. Suakim is conspicuous as the embarking place

for African pilgrims traveling to Mecca. It has a well-protected harbor and is an important shipping point for the products of the interior. These include ivory, tobacco, and gums. The imports for 1899 were valued at $900,000. The trade is increasing. The domestic manufactures are lance-heads, cutlery, and leather cases. Suakim was founded by the Turks, and was a leading slave port until the traffic was suppressed. The vicinity of Suakim was a battle-ground between the Anglo-Egyptians and Osman Digna in 1884 and 1890.

SUANITIANS, or **SWANS.** One of the Georgian peoples of the Caucasus, dwelling in the Transcaucasian Government of Kutais between the Imeritians and the Mingrelians.

SUÁREZ, swä'räth, FRANCISCO (1548-1617). A Spanish theologian and scholastic philosopher. He was born at Granada, entered the Jesuit Order in 1564, and came under the direction of the great ascetic Rodriguez during his novitiate at Medina del Campo. The general of the society, Aquaviva, called him in 1578 to teach in Rome, where he remained seven years. Returning to Spain for reasons of health, he taught at Alcalá, Salamanca, and Coimbra. Besides his thorough knowledge of the Schoolmen, and especially of Thomas Aquinas, whom he usually follows, he displays remarkable familiarity with the writings of the first Christian centuries. His complete works were reprinted in 28 volumes (Paris, 1856-61). Consult Werner, *Franz Suarez und die Scholastik der letzten Jahrhunderte* (Regensburg, 1861).

SUBANDHU, sōō-bŭnd'hōō. A Sanskrit novelist, who lived probably in the seventh century A.D. Apart from a few verses he is known only as the author of the *Vāsavadattā,* a highly artificial romance dealing with the love of Prince Kandarpaketu for the Princess Vasavadatta. The action of the novel is very slight, and the style abounds in long compounds, puns, and assonances. The novel is important in Sanskrit literary history as being the first of the romantic school, and thus being the acknowledged model for the *Kādambarī* and the *Harṣacarita* of Bana (q.v.). It has been edited, with an admirable introduction, by Hall (Calcutta, 1859) and Vidyasagara (ib., 1874), and in Telugu script at Madras (1862). See NOVEL.

SUBANO, sōō-bä'nō. A Malay people in Sibuguey Peninsula, Zamboanga Province, Mindanao. See PHILIPPINE ISLANDS.

SUBCONSCIOUSNESS. A term used somewhat indefinitely to cover weak and obscure mental processes which lie just above the limen of consciousness. Common instances are the sound of a clock and the roar of a stream which pass out of attention if long continued; or the overtones which determine the 'color' or timbre of a musical note, although they are not ordinarily recognized as distinct tonal qualities. Many psychologists hold that subconscious processes, even though they do not attract the attention, do nevertheless exert a determinate influence upon the course of mental events. It is, however, important to distinguish between mind considered for itself alone, without external reference, i.e. consciousness that is properly anoetic, and the vague background against which the more luminous parts of mind are focalized. (See ATTENTION.) The factual existence of obscure processes which elude direct introspection and analysis by the attention is not to be confused with the *hypothesis* of the subconscious, which asserts that all past experience is conserved, not physiologically merely, but in a weakened form of consciousness. Consult: James, *Principles of Psychology* (New York, 1890); Stout, *Analytic Psychology* (ib., 1896). See NOETIC CONSCIOUSNESS.

SUBDEACON. A member of an order in the ministry of the early Church and of the Roman Catholic and Eastern churches at the present day. The subdiaconate apparently originated later than the episcopate, presbyterate, and diaconate, and probably developed from the last named as deacons rose in importance. The function of the office is to assist the deacon, in modern times especially in the celebration of the Eucharist. In the Roman Catholic Church the subdeacon of the mass, who sings the epistle and in other ways assists in the service, is usually a priest. Consult Reuter, *Das Subdiaconat* (Augsburg, 1890), and see ORDERS, HOLY; DEACON.

SUBDOMINANT. The interval one-fifth below the tonic, and the fourth degree of the scale.

SUBIACO, sōō'bē-ä'kō (Lat. *Sublaqueum*). A city in the Province of Rome, Italy, in the Sabine Mountains, 50 miles (of which 36 is by rail, 14 by diligence) east of the city of Rome, on the Teverone (ancient Anio) (Map: Italy, H 6). Here are to be seen walls and terraces of one of Nero's villas, and the famous monasteries of Santa Scolastica (founded in 530) and of San Benedetto. Here in 1465 the Germans Arnold Pannartz and Conrad Schweinheim published the first book printed in Italy, and copies of their editions of Lactantius, Cicero, and Augustine are still in the monastery library, which has lost, however, most of its precious manuscripts. San Benedetto contains thirteenth-century frescoes and paintings. Population (commune), in 1881, 7017; in 1901, 8005.

SUBINFEUDATION (from Lat. *sub,* under + ML. *infeudatio,* infeudation, from *infeudare, infeodare,* to confer in fee, from *in,* in + *feudum,* feud, fee, from OHG. *fihu,* AS. *feoh,* cattle, Lat. *pecu,* Skt. *paśu,* cattle). The act by which a feudal lord granted a portion of his lands to a tenant upon condition that the latter hold of the former subject to the incidents of feudal tenure. This was accompanied with the feudal ceremonies usual in those times. It was by this means that the feudal manors of England were created. As this practice tended to evade the feudal rules against alienation it was forbidden by the famous statute of Quia Emptores. See FEUDAL SYSTEM; MANOR.

SUBJECT (OF. *subject, suject, sujet, suget,* Fr. *sujet,* from Lat. *subjectus,* subject, inferior, p.p. of *subjicere,* to place under, from *sub,* under + *jacere,* to throw). A person who by reason of birth in a country or naturalization under its laws owes allegiance to its sovereign power. The term is almost exclusively employed to denote such a person under a monarchical form of government; whereas, the word citizen is applied to a member of a republic. The rights, privileges and duties of subjects, of course, depend upon the form of government, and they may

differ in political rank and station; thus a duke or an earl is as much a subject of the crown of England as a peasant, although the former is entitled to certain dignities and honors which the latter does not possess. Until comparatively recent times (until 1870 in England) the governments of Europe almost universally refused to recognize the right of a subject to change his allegiance, but they now generally concede this privilege. The policy of the United States in permitting aliens to become citizens by naturalization has probably influenced such nations in changing their arbitrary and despotic attitude on this question, as, of course, it would lead to international difficulties if a naturalized citizen of the United States were to be treated as a subject of the nation whose sovereignty he had renounced in order to become a citizen of the Republic. See ALIEN; ALLEGIANCE; CITIZEN; NATURALIZATION, and the authorities referred to under these titles. Consult Morse, on *Citizenship*.

SUBKINGDOMS, ANIMAL. See CLASSIFICATION OF ANIMALS.

SUBLAPSARIAN. See INFRALAPSARIAN.

SUBLICIAN BRIDGE (Lat. *Pons Sublicius*). The most ancient of the bridges over the Tiber at Rome, ascribed by tradition to Ancus Marcius. The Sublician remained the only bridge at Rome until the second century B.C. It was twice carried away and restored and its piers remained through the Middle Ages. The last remnants were destroyed in 1877.

SUBLIMATION (Lat. *sublimatio*, an uplifting, from *sublimare*, to uplift, from *sublimis*, lofty, from *sub*, under + *limen*, threshold). A term applied to the distillation of those volatile solids that, when heated, pass into the gaseous state without melting. Such substances, including iodine, arsenic (i.e. arsenious acid), the chlorides of iron and aluminus, certain organic compounds, etc., may be readily freed by sublimation from non-volatile impurities. It may be observed that all solids, theoretically without exception, give off more or less vapor, i.e. sublime, even at extremely low temperatures, and of course the evaporation (q.v.) is accompanied by absorption of heat. Ordinarily the rate of evaporation of solids is too small to prevent the temperature from rising to the melting-point on the application of heat. But in the case of solids that are very volatile and have a somewhat high melting-point the heat applied may be largely used up by the rapid evaporation, and so the temperature cannot rise high enough for the substances to melt. Of course, by placing such substances in a closed vessel and thus preventing free evaporation, they may be readily caused to melt.

SUBLIME (from Lat. *sublimis*, lofty). A term applied either to objects arousing a certain æsthetic emotion, or to the emotion itself. The treatise "On Sublimity" ascribed to Longinus (q.v.), but probably belonging to the first century of our era, represents the first attempt to deal with the differentiating characteristics of the sublime. See ÆSTHETICS.

SUBLIME PORTE. See PORTE.

SUBLIMINAL CONSCIOUSNESS (from Lat. *sub*, under + *limen*, threshold). Literally a degree of consciousness below a certain theoretical limit of intensity and clearness.

Such a consciousness cannot be proved to exist by direct introspection, but has been assumed to account especially for four groups of facts. (1) People often execute blind, impulsive actions or feel curious likes and dislikes (e.g. shivering at grating sounds), for which no adequate reason can be found in consciousness. Hence they may be the product of subconscious processes. (2) Many complicated movements, like piano-playing, which at first necessitate highly attentive conscious control, become, with time, decreasingly conscious and finally automatic, yet they seem too complex ever to be purely mechanical. (3) Ideas sometimes appear in consciousness from no assignable source, i.e. neither connected with previous thoughts nor traceable to sense-perception. These may have originated subliminally and thence risen to clear consciousness. (4) A mass of 'borderland' and pathological phenomena, such as automatic writing, trance, post-hypnotic suggestion, double personality, reveals many instances in which complex, seemingly quite intelligent, and hence apparently conscious, actions are executed by individuals who are, nevertheless, entirely ignorant of what they say or do. In the phenomenon of alternating personality such experiences are so frequent and so well organized as to become aggregated into a so-called subconscious 'mind' or 'personality,' which, under certain conditions, e.g. trance, hysteria, and the like, becomes the conscious, dominating personality.

If, with the best authorities, we deny a subliminal consciousness, all four groups of facts must obviously be explained in terms of nervous action without consciousness. Organic tendencies, constitutional dispositions, and various hereditary instincts will then account for the first group of facts, secondary reflexes for the second, inaccurate introspection and unconscious (or marginally conscious) association for the third, and similar principles, supplemented perhaps by neuropathic conditions, for the fourth. The most elaborate argument in favor of a subliminal self is that of F. W. H. Myers.

See ATTENTION; NOETIC CONSCIOUSNESS; SUBCONSCIOUSNESS.

BIBLIOGRAPHY. Carpenter, *Principles of Mental Physiology* (6th ed., London, 1891); Pierce, in *Proceedings of the Society of Psychical Research*, vol. xi. (ib., 1892); Morgan, *Introduction to Comparative Psychology* (ib., 1894); Stout, *Analytic Psychology*, vol. i. (ib., 1896); Myers, *Human Personality and Its Survival of Bodily Death* (ib., 1903); and Flournoy, *From India to the Planet Mars* (New York, 1900).

SUBMARINE BOAT. See TORPEDO BOAT, SUBMARINE.

SUBMARINE GUN (from Lat. *sub*, under + *marinus*, pertaining to the sea, from *mare*, sea). A gun which discharges its projectile beneath the surface of the water. In 1797 a Frenchman, M. Reveroni Saint-Cyr, proposed to arm a catamaran with a submarine gun, but it does not appear that any attempts were made to do so. Robert Fulton and several other Americans attempted the actual construction of effective submarine guns, but with no practical results. Ericsson was the most successful, and his experiments with a submarine gun mounted in

the bow of the specially built vessel the *Destroyer* extended over several years. The difficulty of securing accuracy, the shortness of range, and the improvement of the automobile torpedo have tended to discredit the gun. The *Destroyer* was sold to the Brazilian Government in 1892, but it was never thereafter used, and no subsequent attempts to employ a submarine gun have been made. Torpedoes are now discharged from submerged tubes, but these are not properly guns, as the projectile force is merely sufficient to force the torpedoes clear of the ship's side. See TORPEDO.

SUBMARINE MINES. See TORPEDO.

SUBMARINE TELEGRAPH. See TELEGRAPHY, SUBMARINE.

SUBMAXILLARY GANGLION (from Lat. *sub*, under + *maxilla*, jaw, jaw-bone). One of the four sympathetic ganglia lying in the cephalic region, sometimes called cranial ganglia. The latter term is rather misleading, as none of the ganglia are within the cranial cavity. The submaxillary ganglion is situated above the deep portion of the submaxillary gland. (See SALIVARY GLAND.) It is connected by filaments with the lower border of the gustatory nerve (nerve of taste, supplying the tongue). It also receives motor filaments from the chorda tympani nerve, a branch of the facial. It is small, rounded, and of a reddish-gray color; its filaments of distribution, five or six in number, arise from the lower part of the ganglion, and supply the mucous membrane of the mouth and Wharton's duct, some being lost in the submaxillary gland. The other three ganglia are Meckel's, the ophthalmic, and the otic (qq.v.).

SUBORDINARY. A class of charges in heraldry (q.v.).

SUBORNATION OF PERJURY. The offense of procuring a person to commit perjury. Although only a misdemeanor at common law, in most jurisdictions to-day it is punished with the same severity as perjury. See PERJURY.

SUBPŒNA (Lat. *sub pœna*, under penalty, the initial words of the writ in its original form). A mandatory writ or process issued by a court, a quasi-judicial body, or an official having judicial powers, commanding a person or persons named therein to appear at a certain time and place and testify or furnish documentary evidence in an action or judicial proceeding. Originally a subpœna was used only to compel attendance of witnesses in court, but by statute in most States many officials and bodies having judicial powers, such as boards of commissioners, coroners, etc., are authorized to compel the attendance of witnesses by this process.

A subpœna intended only to compel the attendance of a witness for the purpose of giving testimony is known as a subpœna *ad testificandum*. Where it is necessary to put in evidence documents which are in the possession of a witness, he may be compelled to appear and produce them by a subpœna *duces tecum*. This form of subpœna is substantially like the one above mentioned, except that it specifically enumerates as far as possible the books, papers, and documents desired. In some code States a 'notice to produce' served by one attorney in an action on his opponent serves the same purpose.

In most States a subpœna may be served by any person of discretion, who usually must be eighteen years of age or upward, and service is made by delivering a copy of the subpœna to the witness personally, at the same time showing him the original, and paying or tendering his legal fees and expenses, which are fixed by statute.

Failure to appear in obedience to a subpœna is a contempt of court. It is usual for the party who caused the service of the subpœna to apply to the court for an order directing the witness to show cause why he should not be punished for contempt. Such a witness is also liable in a civil action for all damages which may have been caused by his non-appearance to the party calling him. A witness may be excused, in the discretion of the court, upon showing a reasonable cause for his absence, such as illness, death in family, etc.

Prior to 1852 a defendant was summoned to answer an action in a court of chancery in England by a subpœna *ad respondendum*. This practice has been superseded there by service of a copy of the bill instead, but still obtains in some jurisdictions in the United States. Such a subpœna corresponds more nearly in its purposes to a summons than a subpœna as above described. See SUMMONS; WITNESS; EVIDENCE. Consult the authorities referred to under PROCEDURE.

SUBROGATION (ML. *subrogatio*, from Lat. *subrogare*, *surrogare*, to substitute, from *sub*, under + *rogare*, to ask). The treatment of one who has paid the debt of another, which as between himself and that other should have been paid by the latter, as though he were the assignee of the creditor's claim. The payer is then said to be subrogated to all the rights and remedies of the creditor against the primary debtor. The doctrine upon which this subrogation is based was originally applied by courts of equity, but is now generally applied by courts of law to all cases where one pays a debt on which he is secondarily liable, although the debt may be legally discharged by the payment. Equity, for the purpose of working out justice between the parties by repaying the advances made, deals with the case as though the debt were still in existence, and gives to the person paying the debt precisely the same rights and remedies as belonged to the original creditor, but in no case does one by subrogation acquire any higher or different rights. It will thus be seen that the analogy between subrogation and assignment is complete, one who is entitled to be subrogated to a claim or demand being treated as though he were an assignee of the claim or demand. The only difference between them is the source and not the character of the right, the right to subrogation arising by operation of law and the right of an assignee arising by voluntary act of the parties.

Some of the more important cases in which the doctrine is applied are: (1) Where a junior mortgagor pays off a mortgage prior to his own, when equity will compel an actual assignment of the mortgage by the prior mortgagee. (2) When one pays a debt to the payment of which he is entitled to contribution by others, or for which others are primarily liable and he only secondarily, as in the case of a surety. In these cases, since the sole relief sought is payment of money, courts of law apply the doctrine, and give a complete remedy. (See CONTRIBUTION; SURETYSHIP; QUASI CONTRACT.) (3) In some jurisdic-

tions, particularly in England, when one paying money to a corporation under an *ultra vires* contract cannot recover in quasi contract, although it is used by a corporation in paying its corporate indebtedness, in which case the person so advancing money is subrogated to the rights of the original creditor. (4) In the case of insurance contracts and contracts of indemnity generally whenever the insurer or indemnitor pays the indemnity due under his contract, when he is entitled to be subrogated to the rights of the person indemnified against third parties which may in any manner reduce the loss or obligation indemnified against. See INSURANCE; INDEMNITY; also CHANCERY; EQUITY.

SUBSCRIPTION (Lat. *subscriptio*, from *subscribere*, to subscribe, write under, from *sub*, under + *scribere*, to write). A popular rather than a technical term in law signifying a written contract by which a person agrees to contribute a sum of money for a specified purpose. The subscription may be made either as a gift, or it may be made as an offer to pay the money subscribed in exchange for property to be delivered to the subscriber. Whenever the person or corporation in whose favor the subscriptions are made has performed work or incurred expense or liability, relying upon such subscriptions, the courts have generally held that such expense or liability is a sufficient consideration for the subscription to make it a legally enforceable contract, entitling such persons or corporation to sue upon it. It has also been held that when there are several subscribers and each subscriber has fair notice that others are expected to subscribe to the same object or purpose, the promise of each subscriber is consideration for the promises of all the others. The soundness of such a doctrine may well be doubted and the authorities upon this point are in conflict. A subscription for stock of an existing corporation is generally deemed to be a mere offer which may be withdrawn at any time before acceptance, but which may be accepted at any time before withdrawal of the subscription by an allotment of the stock to the subscriber. Upon such acceptance the subscription becomes a valid contract which may be enforced by the corporation. See CONTRACT; CONSIDERATION.

SUBSIDIES (Lat. *subsidium*, relief, aid, auxiliary force, from *subsidere*, to sit down, remain, subside, from *sub*, under + *sedere*, to sit). A term in English history having reference to special tax assessments upon persons and not directly upon real property; in general European politics it has reference to grants of money to an ally to aid in the prosecution of war; while as a current economic term it applies to grants of money made by the State in aid of individual enterprises.

SUBSIDY AS A TAX. The subsidy was an income tax of 4s. in the pound upon the annual value of lands and a property tax of 2s. 8d. in the pound upon the actual value of goods. In this sense it was first used in the later part of the fifteenth century, but did not come into prominence until the reign of Henry VIII. From then until the Commonwealth it was the most important of the Parliamentary levies. The amount of the subsidy varied. In the eighth year of Elizabeth it brought £120,000; in the fortieth it was not above £78,000; it afterwards fell to £70,000. The subsidy finally became so unequal and uncertain that Parliament changed it into a land tax. This was first done under the Commonwealth, and, owing to its popularity, Charles II. continued it, though he did get one or two grants of subsidy.

SUBSIDIES TO ALLIES. Examples of subsidies of this kind are numerous in English history. Thus during the Seven Years' War England granted large sums to Prussia, one of her allies, as a means of enabling Frederick the Great to cope with his enemies, which included France. Again during the Napoleonic wars England furnished subsidies to several foreign powers.

GRANTS TO INDIVIDUALS. With regard to this class of subsidies, which is by far the most important at present, it may be said that almost the only enterprises that are the direct beneficiaries from Government aid are transportation companies, although it sometimes happens that other enterprises receive indirect benefit on account of Government patronage. Certain bounties, too, very nearly approach the idea of a subsidy. This is especially true of those on beet sugar, which, beginning in the days of Napoleon, have steadily increased in amount, until to-day the question of bounties on sugar has become one of great international importance.

RAILWAY SUBSIDIES. In most of the States of Continental Europe a large part of the original cost of railway construction was defrayed by Government aid. In Great Britain no railroads were subsidized, though some in Ireland were. In Canada the Canadian Pacific received large subsidies in the form of land grants from the Government. In the United States it has been a common practice to encourage and aid railway construction by State and municipal grants, chiefly in the form of subscriptions to their stock. The national Government has also contributed considerable toward the construction of certain railroads, and with one exception this has been in the form of land grants. (See LANDS, PUBLIC.) During the Civil War the importance of attaching the Far West to the Union by means of more direct railroads was seen, and in 1862 Congress passed an act granting to the Union and Central Pacific railroads a subsidy of more than $25,000 per mile in the form of a loan, which it was practically understood would never be repaid, together with 30,000,000 acres of land.

STEAMSHIP SUBSIDIES. See the article SHIPPING SUBSIDIES.

SUBSOILING. See PLOW, PLOWING.

SUBSTANCE (OF. *substance, substaunce*, Fr. *substance*, from Lat. *substantia*, being, essence, material, from *substare*, to stand under or among, from *sub*, under + *stare*, to stand). A term frequently used in logic and metaphysics. Substance is correlative with quality or attribute. Every substance must have attributes, and every attribute must be the attribute of some substance. The substance gold has the attributes weight, color, etc. But as every power or property of a thing, every way that the thing affects us, may be called an attribute or quality, if all the attributes are counted off, there is nothing left except the relations in which they stand to each other. But popular thought and popular philosophy assume that

everything whatsoever possesses, besides its attributes, an unknown substratum; that they rest upon or inhere in a mystical and inscrutable thing, that holds the attributes together, without being itself an attribute.

This view appears at the very dawn of philosophical speculation, having been doubtless an inheritance from pre-scientific and pre-critical thinkers, and has persisted through all the centuries up to the present. It appears in the doctrine of the Ionic philosophers (see IONIAN SCHOOL) as air or earth or water, in Heraclitus (q.v.) as fire, and in Parmenides (q.v.) as pure being. In Aristotle we have a more critical view, according to which the individual realities of experience are substances, while species are second substances. But Aristotle did not answer the question what it is in the individual realities of experience that constitutes their substantiality. The Stoics returned to the idea of a substrate as the bearer of attributes, and this view persisted through the Middle Ages as the only one advocated, except by the Nominalists (see NOMINALISM). In modern philosophy Descartes and Spinoza share this substrate theory. Leibnitz moved away from this static conception and regarded substance as a being capable of action or 'primitive force,' but it was his great opponent Locke who put definitely away the old substrate theory. "All our ideas of the several sorts of substances are nothing but collections of simple ideas, with a supposition of something to which they belong, and on which they subsist, though of this supposed something we have no clear distinct idea at all." "All the simple ideas, that thus united in one substratum make up our complex ideas of several sorts of substances, are no others but such as we have received from sensation or reflection," while "most of the simple ideas that make up our complex ideas of substances, when truly considered, are only powers."

Berkeley went further. Locke had accepted the existence of material as well as spiritual 'powers;' Berkeley maintained that "the supposition of external bodies is not necessary for producing our ideas; since it is granted they are produced sometimes, and might possibly be produced always in the same order we see them in at present, without their concurrence." Hence "there is not any other substance than *Spirit*, or that which perceives." About this substance, however, Berkeley could give no consistent account. At one time we are told that thing or being "comprehends under it two kinds entirely distinct and heterogeneous, which have nothing in common but the name, viz. Spirits and Ideas. The former are active, invisible substances—the latter are inert, fleeting, or independent beings, which subsist not by themselves, but are supported by or exist in minds or spiritual substances." But in another place we are told that "*the soul always thinks;* and in truth whoever shall go about to divide in his thoughts, or abstract the *existence* of a spirit from its *cogitation*, will, I believe, find it no easy task." Hume developed the idea contained in the last quotation and arrived at the result that all substance is an 'unintelligible chimæra.'

Kant emphasized these 'relations' which united perceptions, and found in them the essence of substance. Substance with him is a category of relation, which when schematized, i.e. brought into relation with time and space, becomes "the permanence of the real in time, or the idea of the real as presupposed in the empirical determination of time, and as persisting while all else changes." But this view has a defect. There is too much absoluteness in the conception. It is not necessary that there should be anything which persists through all changes. It is only necessary that there should be some quality which remains *relatively* unchanging, while other qualities change. The quality forms then the nucleus around which the changes gather as variations of a thing. The same thing does not always remain unchanged in the same quality. Now it may be this quality, now that. Were it necessary that some one quality should remain unchanged, that quality would come to be considered the substance of the thing. But the fact that the relatively permanent quality of one stage of change becomes the relatively changing quality of another stage makes it impossible to identify the substance with any one quality. On this account some philosophers prefer to regard substantiality as shifting from time to time.

But perhaps a more satisfactory definition of substance can be obtained from the true theory of judgment. Going back to Aristotle's conception of substance (*οὐσία*) as that of which predication is made, we find (see JUDGMENT) that predication is always made of a synthesis of attributes. The orange of which yellowness is predicated is an object which is yellow, grows on a tree, developed from a flower, is going to be eaten by me next minute, etc. The orange is the synthesis of all these quantities or attributes, some of which may be past and some not yet existent. The only object of which all the qualities of an orange are predicable is the totality of the predicable qualities. This totality exists at any one time, not as a whole, but in part. At no one moment is it consummated as a whole. All the stages of its history are necessary to its totality, but it is not necessary that these stages should be taken out of the real order of succession in which they stand and made to exist contemporaneously before the totality of the process can exist. A temporal whole is from its very nature not a whole at any one time shorter than the whole time of its existence, and the whole time of its existence has within it the distinctions of priority and subsequence which make it impossible to summate the whole into one moment. Now the synthesis of all the qualities which appear to common sense as the qualities of a thing is itself the substance of that thing. Used in this sense substance is no longer what its etymology indicates, viz. a something standing behind phenomena, but it is what the Greek term *οὐσία* means, viz. the being of which attributes are predicable. See PHILOSOPHY; METAPHYSICS; SCHOLASTICISM.

SUBSTANTIVE LAW (Lat. *substantivus*, self-existent, substantial, real, from *substantia*, being, essence, material). That branch or division of the whole law which defines and establishes human rights and privileges with reference to property and prescribes rules of conduct to be observed by mankind in the various relations of life. All other law may be classed as adjective or remedial, that is, as dealing with the methods of enforcement and maintenance of the normal

conditions established by the substantive law, and the rectification of such abnormal social conditions as may arise. For convenience, the substantive law is subdivided into various branches according to the subject matter to which it relates. For example, we speak of the law of real property, of personal property, the law of domestic relations or persons, etc. It is to be found both in legislative enactments and in the rules and precedents of the common law. See LAW and the authorities there referred to.

SUBSTITUTION (Lat. *substitutio*, a putting in the place of another, from *substituere*, to put in the place of another, from *sub*, under + *statuere*, to place, from *stare*, to stand). A mathematical operation by which one expression is replaced by another. The term has, however, come to have a technical meaning in modern mathematics, and this has led to an important branch known as the theory of substitutions. If n elements, $a_1, a_2, a_3, \ldots a_n$ are given, and $a_1, a_2, a_3, \ldots a_n$ and $a_2, a_1, a_3, \ldots a_n$ are two arrangements of these elements, the operation of passing from the first of these arrangements to the second is called a substitution of the n elements. It follows that there are no substitutions of n elements, including the identical substitution, which leaves the order of the letters unchanged. A substitution which in place of the arrangement $a_1, a_2, a_3, \ldots a_n$ gives $a'_1, a'_2, a'_3, \ldots a'_n$, is represented by the symbol

$$\begin{pmatrix} a_1 & a_2 & a_3 & \ldots & a_n \\ a'_1 & a'_2 & a'_3 & \ldots & a'_n \end{pmatrix}$$

If, however, a_1 is replaced by a_2, a_2 by a_3, ... a_{n-1} by a_n, and a_n by a_1, the substitution is said to be *cyclic*, and is more conveniently represented by $(a_1, a_2, a_3 \ldots a_n)$, or even by $(1, 2, 3, \ldots n)$, than by the more elaborate symbol

$$\begin{pmatrix} a_1 & a_2 & \ldots & a_{n-1} & a_n \\ a_2 & a_3 & \ldots & a_n & a_1 \end{pmatrix}$$

Similarly a substitution like $\begin{pmatrix} abcdef \\ cedafb \end{pmatrix}$ may be written $(acd)\,(bef)$, meaning that while a changes to c, c to d, and d to a, b at the same time changes to e, e to f, and f to b. This symbolism is further extended thus: Consider $(ab)\,(ac)$; this means that a changes to b, b to a, and a to c, and c back to a, a result which evidently may also be indicated by (abc), so that $(ab)\,(ac) = (abc)$. But the same reasoning shows that $(ac)\,(ab) = (acb)$. Hence if $s_1 = (ab)$ and $s_2 = (ac)$, $s_1 s_2 \pm s_2 s_1$. For convenience, $s_1 s_2$ is called the *product* of s_1 and s_2 in the order given, from which it appears that the commutative law of multiplication does not hold true in the theory of substitution. If in the product $s_1 s_2 s_3 \ldots s_n$ we have $s_1 = s_2 = \ldots s_n$, the product is called the *power* of each substitution. If a substitution leaves all the elements unchanged in order it is called an *identical* substitution and is represented by 1. If the product of two substitutions, like

$$\begin{pmatrix} a_1 & a_2 \ldots a_n \\ a'_1 & a'_2 \ldots a'_n \end{pmatrix} \text{ and } \begin{pmatrix} a'_1 & a'_2 \ldots a'_n \\ a_1 & a_2 \ldots a_n \end{pmatrix}$$

is 1, each is called the *inverse* of the other, and if the first is represented by s, the second is represented by s^{-1}, ss^{-1} equaling 1.

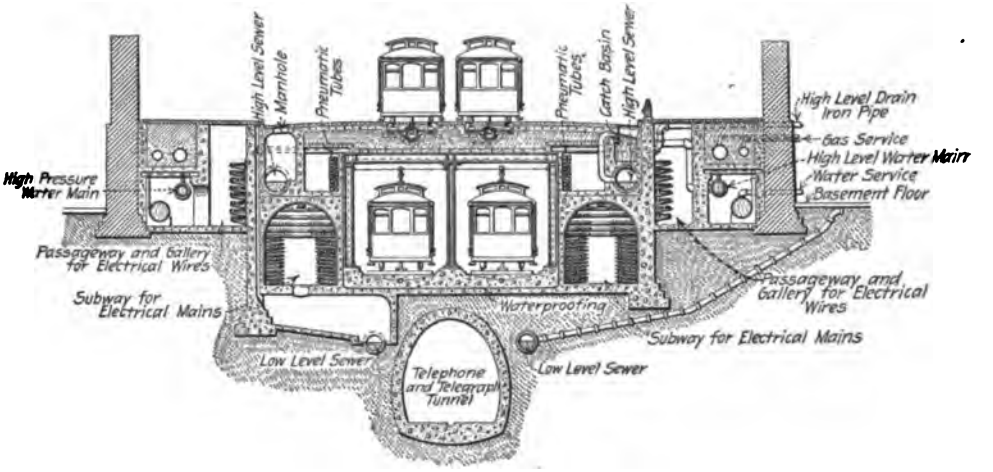
A collection of substitutions is said to form a *group*, if the product of any two is another of the same collection. This may be illustrated outside the field of substitutions by the three cube roots of unity $1, -\frac{1}{2} + \frac{1}{2}\sqrt{-3}, -\frac{1}{2} - \frac{1}{2}\sqrt{-3}$, the product of any two being another of the same collection. The six substitutions $s_0 = 1$, $s_1 = (xyz)$, $s_2 = (xzy)$, $s_3 = x\,(yz)$, $s_4 = y\,(zx)$, $s_5 = z\,(xy)$ also form a group. The number of substitutions of a group is its *order*, and this is always a factor of $n!$. Thus in the group given the order is 6, and this is a factor of 3!. If all substitutions of a group H are contained in another group G, H is called a *sub-group* of G and the order of H is a factor of that of G. A group whose operations are all permutable with one another is called an *Abelian group*.

Lagrange (1770) was one of the first to undertake a scientific treatment of substitutions in connection with the theory of the quintic equation. He invented a 'calcul des combinaisons,' the first real step toward the theory of substitutions. Ruffini (1799) was the next to undertake a serious study of the subject, again in the attempt to show the impossibility of solving the quintic. To Galois (q.v.), however, the honor of establishing the theory is usually ascribed. He found that if $r_1, r_2, r_3, \ldots r_n$ are the n roots of an equation, there is always a group of permutations of the r's such that (1) every function of the roots invariable by the substitutions of the group is rationally known, and (2), reciprocally, every rationally determinable function of the roots is invariable by the substitutions of the group, a discovery that eventually led to the proof of the insolubility of the quintic (Liouville's *Journal*, vol. xi.). Consult also *Œuvres mathématiques de Galois* (Paris, 1897). Cauchy was the first of the well-known French mathematicians to recognize the importance of the theory, and numerous important propositions are due to him (*Journal de l'école polytechnique*, 1815; *Exercices d'analyse et de physique mathématique*, vol. iii., Paris, 1844). Serret was the first to give a connected account of the theory (*Cours d'algèbre superieure*, in the 3d ed., Paris, 1866). This was followed by Jordan's *Traité des substitutions et des équations algébriques* (Paris, 1870). Sylow (1872) was the first to treat the subject apart from its applications to equations (*Math. Annalen*, vol. v.). He was followed by Netto, whose *Substitutionstheorie* (Leipzig, 1882) was translated by Cole (Ann Arbor, 1892), thus making the theory accessible to English readers. Burnside, *Theory of Groups of Finite Order* (Cambridge, 1897), has brought the theory even more prominently before English and American scholars. The first to attempt to simplify the applications of the theory to the subject of equations in an elementary text-book was Petersen, *Theorie der algebraischen Gleichungen* (Copenhagen, 1878).

SUBSTITUTION, THEORY OF. See CHEMISTRY (historical section).

SUBTRACTION (Lat. *subtractio*, a taking away, from *subtrahere*, to take away, from *sub*, under + *trahere*, to draw, drag). The inverse of addition, and one of the fundamental processes of arithmetic and algebra. It is the operation which has for its object, given the sum of two expressions and one of them, to find the other. The given sum is called the *minuend*, the given addend is called the *subtrahend*, and the addend

to be found is called the *difference* or the *remainder*.



SUBURRA. A district of ancient Rome in the valley between the Esquiline, Quirinal, and Viminal Hills. It was thickly populated and bore an evil reputation as the resort of peddlers, footpads, and prostitutes.

SUBWAYS (FOR PIPES AND WIRES). Underground galleries which contain and render accessible at any point the multitudinous pipes and wires beneath city pavements; or else ducts for inclosing underground wires only, in such a way as to make them accessible at intervals. Subterranean passages for the accommodation of street traffic are either nothing more than streets or footpaths placed in tunnels, which need no description, or they are underground railways, which are described in the article on TUNNEL.

The chief advantages of subways for pipes and wires are: (1) They increase the life and general serviceability of pavements and prevent the interruption to traffic caused by street excavations to gain access to pipes when simply buried in the ground. (2) They facilitate both the inspection and repair of all classes of underground furniture, and thus lessen the number of troublesome and dangerous leaks from water and gas mains; they also aid in the prevention of electrolysis, or the electrical decomposition of iron and lead conduits through stray electrical currents from overhead trolley systems. (3) Ventilated and relatively dry subways may greatly lengthen the life of pipes and wires through better protection against corrosion than is possible when such furniture is laid directly in the earth.

One of the earliest attempts to avoid the disturbance of pavements was carried out in Liverpool, where a gallery 2½ feet wide was built under the sidewalk and in it were placed an oval pipe sewer 27×18 inches, a 10-inch water main, and a 10-inch gas main. The bottom of the trench was 13 feet below the surface of the sidewalk. Little or no provision for repairs was made. The London subways date from 1861 or 1862, when one was built in a new street from Covent Garden Market to Saint Martin's Lane. A few months later a subway was built at Nottingham, England. Subsequently a number of subways were added to the first ones built in London and Nottingham. The London subways range in size from 14 feet wide and 7 feet high to 8×7 feet. The walls are of brick, laid in cement. The roofs are formed by semicircular brick arches, with ventilators extending to the streets at intervals of 100 feet. The London subways contain gas, water, electric light, hydraulic power supply, telephone, and telegraph mains. The placing of wires and a great variety of pipes in the sewers of Paris is one of the notable features of that city.

In the United States the nearest approach to subways like those of Europe is at Saint Paul, where a number of miles of sewers have been constructed in the form of tunnels in the soft sand-rock which underlies the city, and water mains have also been placed, separately, in similar tunnels. Branch tunnels connect with the houses, in the same general way as branches lead to the buildings along the line of the European subways. Besides the sewers and water mains at Saint Paul some private companies have placed telephone lines in like tunnels. Tunnels for telephone cables have been constructed in Chicago.

CROSS-SECTION OF CHICAGO STREET, SHOWING PROPOSED ARRANGEMENT OF SUBWAYS.

ELECTRICAL SUBWAYS. Although there are no instances of subways for both pipes and wires in the United States, the practice of putting wires underground is rapidly growing. It is getting to be a comparatively common practice, even in small towns, for telephone companies to bury their wires; and though the work is often done cheaply and rather crudely, the wires are nevertheless removed from overhead and at the same time are so arranged that little subsequent disturbance of the street is necessary. In a growing number of the larger cities electrical wires for light and power, together with the ordinary and the police and fire alarm telegraph lines, are also placed underground. Electrical subways consist of a single pipe or tube, or a group of such, designed to protect underground wires from injury due to settlement of the earth or the picks and shovels of workmen. At the same time these subways afford access to the wires through manholes placed at intervals, for repairs, connections, or the drawing in of new wires. Some

of the underground systems have the conductors built in the tubes before the latter are laid, in which case new wires cannot be added without laying additional tubes, but provision is made for service connections without digging up the street. The most common materials used for the conduits or ducts are wrought iron, earthenware, and wood, but sometimes cast iron, and again ordinary or more rarely bituminous cement concrete is used. In place of tubes troughs of cast iron, earthenware, or wood, covered with the same material, are sometimes employed. The diameters of the various ducts are about three inches, and if one is not sufficient for the various wires to be buried any desired number may be placed in the same trench. Wrought iron pipes similar to gas pipes are commonly imbedded in concrete, and they may be laid in trenches lined with cement or wood. Earthenware or terra-cotta ducts are generally surrounded with concrete, but the latter sometimes gives place to boards at the top. Each piece of conduit is eighteen inches long. If a group of ducts is desired they are laid up one on another, breaking joints, much like brickwork; or multiple ducts may be bought from the manufacturers. Concrete ducts are formed in place. Wooden ducts are in the form of square timber, with holes bored through the centre, or constructed more cheaply from boards. Wood-fibre pipes are also used. (See PIPE.) In the Edison three-conductor tube system three copper rods are so wound, separately and collectively, with rope, as to insulate them from wrought iron pipe, some twenty feet long, in which they are placed. These sections are filled with a fluid insulating compound before being shipped from the factory. Special insulated joints are made in the trenches, both for ordinary joints and for branch lines. Edison tubes of a simpler type but embodying the same principles are also made. The various classes of electrical wires and cables are generally insulated before being placed in subways. (See ELECTRIC LIGHTING; ELECTRIC RAILWAYS; TELEGRAPH; TELEPHONE, etc.) The wires and cables are drawn into the closed electrical subways through manholes at intervals of 200 to 300 feet by means of ropes or rods. If ropes are used a steel wire with a round metal head is first pushed through, and by means of this a rope sufficiently large to haul the electric cable is drawn in. The rods are pushed through from manhole to manhole, one short rod after another being jointed onto the line. Ordinarily electrical subways need be placed but three feet or so underground.

Consult: Mason, "Street Subways for Large Towns," and discussion thereon, in *Transactions of the Society of Engineers* (London, 1895); article in *Engineering News* on "Street Subways for Pipes and Wires" (New York, March 15, 1900), describes all subways for both pipes and wires known to be in use up to early in 1900; also chapter on underground electrical construction in vol. ii. of Crocker, *Electric Lighting* (New York, 1901), and similar chapters in Hopkins, *Telephone Lines and Their Properties* (ib., new ed., 1901).

SUCCESSION (Lat. *successio*, from *succedere*, to follow, succeed, from *sub*, under + *cedere*, to yield). At civil law (q.v.) succession signifies in general the substitution of one person for another in an existing legal relation. Acquisition of a right previously held by another is termed *active* succession; subjection to a duty previously resting upon another, *passive* succession. When single rights or duties are thus transferred the succession is said to be *singular*. When a person receives all the rights and duties of another that are capable of transfer the succession is said to be *universal*. The most important case of universal succession is inheritance, which at civil law signifies the transfer to one or more heirs of the rights and obligations of a person deceased. Heirs may be designated by a last will or testament (q.v.); in the absence of a valid testament they are designated by general laws. In the latter case civilians speak of inheritance or succession *ab intestato* (q.v.). Inheritance may also be determined, in part, by laws which give certain persons rights of succession of which they cannot be deprived by a testator except on legally defined grounds. For such limitations upon the power of testation at civil law, see TESTAMENT.

SUCCESSION AB INTESTATO (Lat., from one intestate). I. ROMAN LAW. In early Roman law, as in early law in general, succession was governed by the organization of the family. According to the Twelve Tables the inheritance vested (1) in the *sui*, i.e. the members of the decedent's family, who were under his household authority. (See PATRIA POTESTAS.) The sons and the unmarried daughters and the widow who had been *in manu* (see MARRIAGE) had equal shares. Children of a pre-deceased son received their father's share. Failing *sui*, the inheritance passed (2) to the nearest agnate (i.e. the nearest collateral relative in the male line). If there was no agnate the inheritance went (3) to the *gens* or clan. Under this system kinship gave no right except in so far as it coincided with the family organization. Emancipated sons and daughters, married daughters and their descendants, and all cognates (relatives in the female line) were excluded from succession. On the other hand, adopted children and the wife *in manu* had the same rights as the other *sui*. In the subsequent development of the law there was a steady movement toward fuller recognition of kinship. This movement began with the prætorian reforms at the close of the Republican period. Emancipated sons and daughters and married daughters were admitted to inherit with the *sui*, on condition of 'collating' (i.e. putting into hotch-pot) their separate property. Failing agnatic relatives, cognates were admitted; and failing cognates, the husband and wife who had established a free or 'consistent' marriage succeeded one to the other's estate. Later Imperial legislation placed cognates and agnates on the same footing, as far as the direct line was concerned (ascendants and descendants). Justinian in his 118th Novel abolished all preference of agnates. Under Justinian's rules the inheritance went (1) to descendants; (2) to ascendants, brothers and sisters of the full blood and their children; (3) to brothers and sisters of the half blood and their children; (4) to the nearest collateral relative; (5) to the surviving spouse; and (6) to the fiscus. Illegitimate children had no rights of succession except from the mother.

II. MEDIÆVAL EUROPEAN LAW. The early

German law of inheritance, with the Roman, was based on the family, but it gave no such preference to kinship in the male line, except as regarded succession to real property. As regarded such property, however, a preference not only of the male line over the female, but of male heirs over female, is visible in the earliest written laws; and this preference was emphasized and made general in mediæval Europe by the development of the feudal system. In German law there appeared also a distinction between sword-goods and spindle-goods, i.e. between things used by men and things used by women, and a tendency to prefer male heirs as regarded sword-goods and female as regarded spindle-goods. Another German idea was that, when the nearest heirs were of the half blood, property that had come to the decedent from the father's side should go to the paternal relatives, while property that had come from the mother's side should go to the maternal relatives ('paterna paternis, materna maternis;' in Spanish law, 'troncalidad'). Sporadically manifested, moreover, was a disinclination to allow property to ascend, with resultant rules preferring brothers and sisters and their descendants to parents.

As between collaterals rights of succession at German law did not depend wholly on nearness of kinship. Descendants of a nearer common ancestor were regularly preferred to descendants of a more remote common ancestor. Inheritance vested (1) in descendants of the decedent; (2) in descendants of his parents; (3) in descendants of his grandparents; (4) in descendants of his great-grandparents, and so on. Within each such group the nearest of kin took the inheritance. This is described by modern writers as the 'lineal-gradual' or 'parentela' system. Coupled with a preference of the male line and of males within that line it became the (original) feudal law of succession, and (with preference of the eldest male added) it determined the English law of inheritance of real property.

III. Modern Civil Codes. In modern European legislation the Roman principle of universal succession has generally reasserted itself: the same rules generally govern inheritance of realty and of personalty. In all the codes the inheritance vests primarily in descendants. Failing these different rules prevail. At French law the inheritance passes, in second instances, to parents, brothers, and sisters and the children of brothers and sisters, all of whom take precedence of grandparents. The Spanish code prefers all ascendants, and the German code prefers parents, to brothers and sisters. In the absence of descendants, ascendants, and of brothers and sisters and their descendants, the French, Italian, and Spanish codes confer the inheritance upon the nearest collateral; but the French code provides that if there be collaterals both on the paternal and the maternal side the inheritance shall be divided. The Austrian and the German codes follow the parentela system.

The surviving spouse is better treated than at Roman law. Under the Code Napoléon, indeed, the surviving spouse had no right except by ante-nuptial contract or, in the absence of such contract, by operation of the general law of matrimonial property; but by the law of March 9, 1891, he or she has a life interest in a portion of the property, which is at most one-fourth if there are children, but rises to one-half if there are no children. There are similar provisions in the Italian and Spanish codes; but at Spanish law if the decedent has neither descendants, ascendants, nor brothers or sisters or nephews, the surviving spouse takes the whole estate absolutely; and at Italian law, if there are no legitimate children, the surviving spouse takes from one-fourth to one-third absolutely as against parents and illegitimate children, two-thirds as against collaterals, and the whole estate if there is no collateral within the sixth degree (e.g. a second cousin). The German law is even more liberal: the surviving spouse takes one-fourth absolutely as against children; one-half to three-fourths as against parents, brothers and sisters, and grandparents; and the whole as against the decedent's other relatives.

As to illegitimate children different rules prevail. The French, Italian, and Spanish codes give no rights of inheritance to such children unless they have been 'recognized.' Such a recognized child inherits in concurrence with legitimate children, taking, however, only half the share of a legitimate child. When there are no legitimate children the rights of recognized illegitimate children are greater. By the French law of March 25, 1816, they take the whole estate as against all collaterals, except brothers and sisters and their children. In the German code the illegitimate child, although 'recognized,' has no right of succession in the estate of his father or in those of his father's relatives; but in the mother's estate and in those of her relatives such a child has the same rights as if born in wedlock. For a treatment of subjects in English and American law, see Descent; Distribution; Heir; and Inheritance.

SUCCESSION WARS. The name given to wars arising out of conflicting claims of succession to the throne. Among such wars that have been waged in Europe the following deserve special notice: (1) The War of the Spanish Succession, 1701-14; (2) that of the Polish Succession, 1733-35; (3) that of the Austrian Succession, 1740-48; and (4) that of the Bavarian Succession, 1778-79.

The War of the Spanish Succession arose on the death without male heirs of Charles II. (q.v.), King of Spain, of the House of Hapsburg, November 1, 1700. The nearest natural heir to the throne was of the royal Bourbon line of France, Charles's elder sister having married Louis XIV.; but, to prevent any possible union of the two crowns, a solemn renunciation had been exacted both from Louis and his Queen, for themselves and their heirs. Failing the Bourbons, the next heirs were the descendants of the younger sister of Charles, who had married the German Emperor Leopold I., ruler of the Austrian realm, and from whom no renunciation had been exacted; and the only issue being a daughter, who had married the Elector of Bavaria, and borne a son, Joseph Ferdinand, this prince was during his lifetime regarded both by Charles II. and the Spanish people as the rightful heir. As he died in 1699, the question of succession was reopened. Louis XIV. claimed the throne for himself, as the son of Philip IV.'s eldest sister, being, however, again legally barred here by another solemn renunciation. The Emperor Leopold maintained that the Bourbons had by these two renunciations lost all rights of succession,

and he claimed the throne as the son of Philip IV.'s younger sister. (See genealogical table, *The Hapsburg Family*, under HAPSBURG.) Leopold handed over his claim to his second son, the Archduke Charles. The Austrian party at first preponderated in Spain; but Louis succeeded in undermining the Austrian influence, and his grandson, Philip of Anjou, was declared the heir (October 2, 1700). On the death of King Charles, Philip appeared in Spain and was recognized as monarch. The Emperor Leopold at once took up arms and sent an army into Italy under Prince Eugene, who defeated the French general Villeroi at Chiari on September 1, 1701. William III., regarding the union of France and Spain under the Bourbons as a menace to the naval interests of England and Holland, and stirred up by the action of Louis XIV. in recognizing the Pretender, James Edward Stuart, determined to revive the Grand Alliance against France, and entered into a coalition with Austria and her allies in the German Empire, including Prussia. Savoy, Bavaria, and some of the other German States joined the Bourbons. William's policy was continued by Queen Anne, who succeeded to the English throne in March, 1702, and immediately declared war.

In 1702 Churchill (the future Marlborough), at the head of an English-Dutch-German army, made a victorious advance against the French in the Spanish Netherlands; while a German army under the Margrave of Baden crossed the Rhine and encountered Villars, who proved too powerful for him. In Italy, Prince Eugene, after taking Villeroi prisoner at Cremona (January, 1702), was checked by Vendôme. In 1703 Marlborough gained fresh successes and the Duke of Savoy joined the Grand Alliance. The first great blow was struck on August 13, 1704, when the combined Austrian-German-British army under Marlborough and Prince Eugene totally defeated the French and the Bavarians under Tallard at Blenheim (q.v.). A few days before Gibraltar had fallen into the hands of the English. The campaigns of Marlborough in Germany and of Eugene in Italy in 1705, while successful, were not very important. In 1706 Marlborough suddenly attacked the French and Bavarians under Villeroi at Ramillies (q.v.), and routed them with great slaughter. The victory of Eugene over Marsin at Turin in the same year shattered the French power in Italy.

In the meanwhile in 1704 the Archduke Charles landed at Lisbon with a British and Dutch army and invaded Spain. In the following year the Earl of Peterborough and Sir Clowdisley Shovell landed with a small body of troops in Catalonia. Then, attacked from both east and west, the Bourbon forces were beaten and driven across the Pyrenees. After the departure of Peterborough, however, the Bourbon commander, the Duke of Berwick (q.v.), made head against his antagonists, and by his victory at Almanza (April 25, 1707) he recovered the whole of Spain except Catalonia. In the Netherlands Marlborough and Prince Eugene fell upon Vendôme's army at Oudenarde (1708) and inflicted upon it a severe defeat. The capture of Lille, Ghent, and Bruges followed. France now began to show symptoms of exhaustion, and made overtures of peace, but the demands of the allies were of so exorbitant a character that Louis XIV. preferred to continue the war. The French under Villars suffered another great defeat in September, 1709, at the hands of Marlborough and Prince Eugene at Malplaquet (q.v.). The death of the Emperor, Joseph I., the successor of Leopold I. (April 17, 1711), and the accession in the Austrian dominions and in the German Empire of his brother, Charles VI., came to the rescue of France, for England became immediately lukewarm in support of a cause the success of which would result in the union of Austria and Spain; and the English Tories having come into power, England concluded an armistice with France in 1712. Prince Eugene still carried on the war, aided by Holland, but was compelled to give way; and in the following spring (1713) Holland, Prussia, and Savoy joined England as parties to the Peace of Utrecht (q.v.). The Emperor Charles VI. found himself forced to conclude a treaty of peace at Rastatt, March 7, 1714, and later on the more formal treaty of Baden (in Aargau), September 7, 1714, ended the struggle, leaving Philip in possession of the Spanish throne, but with the provision that the crowns of France and Spain should never be united in the same person, while Austria obtained the Spanish Netherlands, the former Duchy of Milan, Naples, and Sardinia. Sicily was awarded to Savoy, which exchanged it for Sardinia. Gibraltar and Minorca were ceded to England, which acquired Arcadia from France. The conflict waged between the English and French in America as part of the War of the Spanish Succession is known as Queen Anne's War.

Consult: Stanhope (Lord Mahon), *History of the War of the Succession in Spain* (London, 1836); Coxe, *Memoirs of the Kings of Spain of the House of Bourbon* (ib., 1813); Von Noorden, *Europäische Geschichte im 18ten Jahrhundert*, "Der spanische Erbfolgekrieg" (Düsseldorf, 1874-83), perhaps the best work on the subject. See LOUIS XIV.

THE WAR OF THE POLISH SUCCESSION. In 1733 Augustus II. of Poland and Saxony died and Stanislas Leszczynski (q.v.), whose daughter had married Louis XV. of France, was elected King by the Diet through French influence. Some of the nobles, however, were determined that the crown should pass to Augustus (Frederick Augustus II. of Saxony), son of the late King. Russia and Austria supported Augustus and a Russian army placed him on the throne. Stanislas withdrew to the fortress of Danzig, where he held out until June, 1734. France, in retaliation for Austria's support of Augustus III., declared war on the Emperor. The French forces invaded Lorraine and fought successfully on the Rhine (1733-34). Charles Emmanuel III. of Sardinia took up arms against Austria, and in 1734 Don Carlos, son of Philip V. of Spain, seized the opportunity to undertake the conquest of the Two Sicilies, which had been wrested from Spain in the War of the Spanish Succession. The Austrians were overthrown at Bitonto on May 25, 1734, and in 1735 Don Carlos was crowned King of the Two Sicilies. By the preliminaries of Vienna (October 3, 1735), Austria relinquished the possession of these regions. Augustus III. was recognized as King of Poland, though Stanislas retained the royal title and was given for his life the duchies of Lorraine and Bar, which

were afterwards to revert to France. Francis Stephen, the dispossessed Duke of Lorraine, received the Grand Duchy of Tuscany as compensation. France lent its guarantee to the Pragmatic Sanction (q.v.) and Parma and Piacenza were handed over to the Emperor by Don Carlos. The definitive Peace of Vienna was not signed till 1738.

THE WAR OF THE AUSTRIAN SUCCESSION. This struggle arose after the death of the Emperor Charles VI. (q.v.), in 1740. In accordance with the Pragmatic Sanction (q.v.) Charles VI.'s daughter and heiress, Maria Theresa, had received assurances of support from most of the European powers, but hardly had she ascended the Austrian throne when she found her dominion contested on every side. Frederick the Great of Prussia reasserted an old claim and invaded and seized Silesia. Charles Albert, Elector of Bavaria, claimed to be the rightful heir to the Hapsburg possessions as a descendant through the female line of Ferdinand I., and in virtue of old arrangements. Augustus III. of Saxony and Poland put forward his claims as the husband of the eldest daughter of the Emperor Joseph I. The Bourbon courts of France and Spain seized the opportunity to make war upon Austria. England thereupon entered into an alliance with Maria Theresa. Charles Emmanuel III. of Sardinia was also among the princes who sought the dismemberment of the Austrian realm. Holland joined the Anglo-Austrian Alliance, and the Bourbon King of Naples joined the enemies of Maria Theresa. Some of the minor German princes engaged in the struggle, as allies of Prussia and France. On April 10, 1741, Frederick II. defeated the Austrians at Mollwitz. The Bavarians, the French, under Belleisle, and the Saxons poured into the Austrian dominions. Maria Theresa appealed for support to her Hungarian subjects at the Diet assembled at Pressburg and they responded chivalrously to her call. She was, however, unable to save Prague, which surrendered to Belleisle on November 26, 1741, but at the beginning of 1742 her forces entered upon a victorious campaign against Charles Albert. General Khevenhüller overran Bavaria, and on the very day of the Elector Charles Albert's coronation as Emperor Charles VII. took Munich (February 12, 1742). On May 17, 1742, Frederick won a victory over the Austrians at Chotusitz, which was followed by the Treaty of Breslau (terminating the first Silesian War), which provided for the cession of most of Silesia to Prussia. The French General Belleisle effected a masterly retreat from Prague.

In May, 1743, Bavaria again fell into the hands of the Austrians. In June the English, under George II., defeated the French at Dettingen. In the same year Saxony and Sardinia were won over to the side of Austria. France and Spain now remained the sole representatives of the coalition. Seeing the tide turn so strongly in favor of Austria, Frederick became alarmed and renewed hostilities in 1744 by an invasion of Bohemia (second Silesian War). In January, 1745, Charles VII. died and his son, Maximilian Joseph, made peace with Austria. On June 4, 1745, Frederick won a victory over the Austrians at Hohenfriedberg, and on December 15th the Prussians defeated the Saxons at Kesselsdorf. Frederick, displeased with the overbearing conduct of France, was willing to make terms with Austria, and the Peace of Dresden (December 25, 1745) between Austria, Saxony, and Prussia terminated the second Silesian War. On September 13, 1745, the husband of Maria Theresa had been elected Emperor as Francis I. In the meanwhile the French were being led to victory in the Austrian Netherlands by Marshal Saxe, who, on May 11, 1745, defeated the English, Hanoverians, Dutch, and Austrians at Fontenoy. One after another the principal towns of the region fell before his attacks, and on October 11, 1746, he won a splendid victory over the allies under Charles of Lorraine at Raucoux. In Italy the war was waged with varying fortune. In 1745 the French were successful. In 1746 the Austrians and Sardinians made a victorious advance, and Genoa, which had joined the enemies of Austria, was occupied. The city, however, had soon to be evacuated, and an attempt to recapture it in 1747 was frustrated by the French. In 1747 Saxe routed the Duke of Cumberland at Laffeld, near Aix-la-Chapelle (July 2d), while his celebrated chief of engineers, Count Löwendal, after a two months' siege, took Bergen-op-Zoom, a fortress believed by the Dutch to be impregnable. On the sea, however, the English gained victories in 1747 under Admirals Anson and Hawke. At this juncture the Empress Elizabeth of Russia came to the aid of Maria Theresa and sent her forces into the field. France was now willing to listen to proposals of peace. On October 18, 1748, the Treaty of Aix-la-Chapelle put an end to the war. It left the Hapsburgs in possession of their hereditary dominions, with the exception of Silesia. Parma and Piacenza (acquired in 1735) were handed over by Austria to Don Philip, brother of Ferdinand VI. of Spain. The principal event of the contest waged by the British and French in America (King George's War) was the taking of Louisburg in 1745. The French held their ground in India.

THE WAR OF THE BAVARIAN SUCCESSION. The Elector Maximilian Joseph of Bavaria died without issue on December 30, 1777. The natural heir was Charles Theodore, Elector Palatine, head of the elder line of the House of Wittelsbach.

This prince had no legitimate heirs, and with a view of furthering the interests of his illegitimate children, he had, in January, 1778, entered into a convention with the Emperor Joseph II. (the son of Maria Theresa, sovereign of Austria and Queen of Hungary) by which he agreed to transfer Lower Bavaria to Austria, which put forward an antiquated claim to a part of the Bavarian dominions. Frederick the Great would not consent to such an aggrandizement of Austria in South Germany, the more so as he felt that it might interfere with the claim of Prussia to the succession in the principalities of Ansbach and Bayreuth. As Austria refused to withdraw her pretensions, Frederick proceeded to make war on her, and in the summer of 1778 he invaded Bohemia. He was joined by the Elector of Saxony, who, as the husband of the only daughter of Maximilian Joseph, claimed a portion of the Bavarian inheritance. Maria Theresa and Joseph II. were in no haste to plunge into a war. Prussia, and the Austrian forces confronted the enemy without coming to an en-

gagement. The hostile attitude of Catharine II. of Russia toward Austria induced her to give way, and in the Treaty of Teschen, signed on May 13, 1779, she had to content herself with the acquisition of the Innviertel, a district on the east side of the Inn, with the exception of which the whole of the Bavarian inheritance passed to Charles Theodore. The Elector of Saxony received a money indemnity.

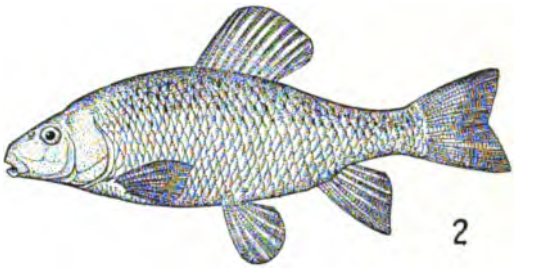
SUCCINIC ACID (from Lat. *succinum, sucinum*, amber), $COOH.CH_2.CH_2.COOH$. A di-basic organic acid found in amber, in unripe fruits, in brown coal, etc. In the animal organism it occurs in the spleen, the hydrocephalic and hydrocele fluids, and, according to some authors, also in normal urine. It has been known to chemists since the sixteenth century, and its acid character was discovered by Lemery in 1679. It may be obtained by a variety of synthetic chemical methods. Usually, however, it is prepared by the fermentation of a solution of ammonium tartrate. It is a crystalline substance melting at 180° C. and boiling at 235° C., though when distilled it loses the elements of water and is partly converted into its anhydride. Succinic acid is almost insoluble in ether; it is moderately soluble in cold and very soluble in hot water and alcohol.

SUCCORY. Another name for chicory (q.v.).

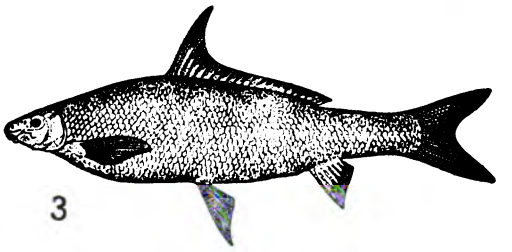
SUC'COTH (Heb. *sukkōth*, booths, thickets). A place name occurring several times in the Old Testament. In Joshua xiii. 27 a Succoth is described as situated in the territory of Gad, 'in the valley,' and within the ancient bounds of Sihon, King of Heshbon. A location east of the Jordan is indicated here and also in Genesis xxxiii. 17 and Judges viii. 5-16 (cf. Psalms lx. 6, cviii. 7). In I. Kings vii. 46 (II. Chron. iv. 17) it is stated that the metal work for Solomon's temple was cast "in the plain of Jordan between Succoth and Zarthan." It has been thought that this Succoth was in the west Jordan country. No satisfactory identifications, however, have been proposed. Succoth was also the name of the second station in the Exodus from Egypt (Ex. xii. 37, xiii. 20, Num. xxxiii. 5-6).

SUC'COTH-BE'NOTH. According to II. Kings xvii. 30, the name of a deity whose worship was carried on at Samaria by the colonists from Babylon settled there by Shalmaneser IV. No such god has been found in Babylonian inscriptions, and it is reasonable to conclude that the form is corrupt. In Amos v. 26 a deity (or a star), Sikkut, is mentioned by the side of Chiun (perhaps the planet-god Saturn-Ninib), and a deity Sakkut occurs in Babylonian literature. The bad state of the text in the passage from Amos, however, requires caution in drawing conclusions, and there is no necessary connection between Succoth and Sikkut.

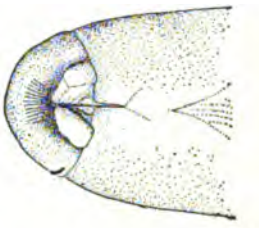
SUCHER, sōō'kĕr, JOSEF (1844—). A prominent Austrian musical conductor and composer, born at Döbör, Eisenburg County, Hungary. First instructed in music as a chorister in the Imperial chapel at Vienna, he afterwards studied law at the university and composition under Sechter, became conductor of the Akademische Gesangverein and assistant conductor at the opera, and in 1876 went to Leipzig as kapellmeister at the Stadt Theater, where his rehearsals of Wagner's music dramas, especially of the *Ring of the Nibelung*, placed him in the front rank of modern conductors. In 1879 he was called to Hamburg and in 1888 to the Royal Opera in Berlin. As a composer he has earned reputation through choral and orchestral works, church music, and many lofty and spirited songs.—His wife, ROSA (1849—), born (Hasselbeck) at Velburg, Upper Palatinate, is a highly gifted dramatic singer, widely known as an interpreter of Wagner rôles. She appeared first in Munich, was subsequently connected with the stages at Treves, Königsberg, and Danzig, then at Leipzig, where she was married, and went with her husband to Hamburg and Berlin. Since 1898 she confined herself to starring engagements, notably for the Festspiele at Bayreuth, her impersonations of Isolde, Sieglinde, and Brunhilda being most highly commended.



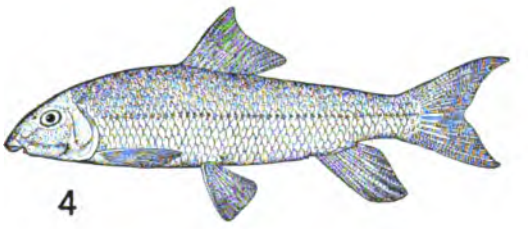
SUCHET, sü'shâ', LOUIS GABRIEL, Duke of Albufera (1770-1826). A marshal of France, born at Lyons, March 2, 1770. He began his military career by volunteering as a private in the Lyons National Guard in 1792. His intelligence and valor at Lodi, Rivoli, Castiglione, Arcole, and in battles of less note, laid the foundation of his military reputation. In 1797 he became a general of brigade and in the following year general of division, serving in Switzerland and Italy. In 1800 he kept Melas in check, with a force far inferior to that of the Austrian commander, and prevented the invasion of France. He took part in the campaigns against Austria (1805) and Prussia (1806-07), was sent to Spain in 1808, and in 1809 was appointed to the command of the French army in Aragon. He won the battle of Belchite (June 16-18, 1809) and took Lérida (May, 1810), and Tortosa and Tarragona (1811), earning the marshal's baton for his achievements. In January, 1812, he conquered Valencia, and was made Duke of Albufera. The misfortunes of the other French armies in Spain compelled Suchet gradually to relinquish his conquests. He was created a peer by Louis XVIII., but took service under Napoleon after his return from Elba, and was charged with the defense of the southwestern frontier. Deprived of his peerage at the Second Restoration, he did not return to Court till 1819. He died at the Château of Saint-Joseph, near Marseilles, January 3, 1826. Consult Suchet, *Mémoires sur ses campagnes en Espagne* (Paris, 1829-34).



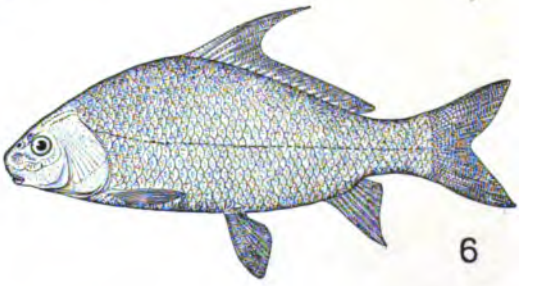
SUCHIER, su'shyâ', HERMANN (1848—). A German Romance philologist, born at Karlshafen, Hesse-Nassau, of a family of French refugees. After studying at Marburg and Leipzig, he qualified at Marburg in 1873 and became successively professor at Zurich (1875), Münster, and Halle (1876). Of his publications in the field of French and Provençal philology may be noted: "Ueber die französische Sprache," in Gröber's *Grundriss der romanischen Philologie* (1888), also separate in French, *Le Français et le Provençal* (1891); *Altfranzösische Grammatik* (1893). He edited *Aucassin et Nicolette* (4th ed., 1899); *Bibliotheca Normannica* (1879); *Denkmäler provençalischer Litteratur und Sprache* (1883); *Œuvres poétiques de Philippe de Remi* (1884-85). In collaboration with Birch-Hirschfeld he wrote a *Geschichte der französischen Litteratur* (1900).

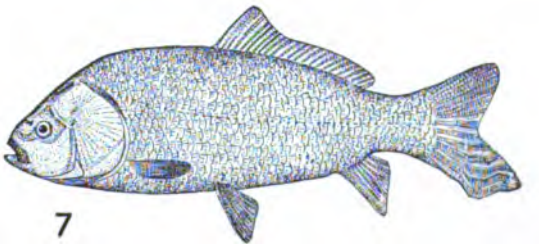


SU-CHOW, sōō'chou', or **SOO-CHOW.** A *fu* or departmental city of the Province of Kiang-su,



SUCKERS





1. RAZOR-BACKED SUCKER (*Xyrauchen cypho*).
2. CHUB SUCKER (*Erimyzon sucetta*).
3. MISSOURI SUCKER (*Cycleptus elongatus*).
7. BUFFALO

CUTLIPS (*Lagochile lacera*).
LIPS (No. 4).
(*Carpiodes cyprinus*).

China (Map: China, F 5); the residence of the provincial judge, the *chih-fu* or head of the department of the same name, and three district magistrates. It is situated on the Grand Canal, 80 miles west of Shanghai and 40 south of the Yang-tse. Its walls are 30 feet high, are pierced with 6 gates and 5 water-gates, and have a circuit of 12 miles. Outside of five of these gates are large suburbs, the largest and busiest being that outside of the northwest gate or Ch'ang-mên, within which is the chief business quarter of the city. Su-chow was founded about B.C. 500. It is a great commercial and manufacturing place, and is the centre of a great silk and satin industry in which thousands of looms are employed. It has also steam factories, two cotton mills, a flour mill, and thousands of workers in wood, gold, silver, brass, iron, tin, ivory, glass, lacquer, etc. It has long been noted for its wealth and luxury, and the gayety and elegance of its life and manners. In 1860 it was captured by the Taiping rebels and reduced almost to a heap of ruins. Among the buildings that escaped destruction is a pagoda 240 feet in height, said to be the highest in China. There are several others both within and without the city. The streets are not wide enough for much traffic, but a great network of canals ramifies through the city and the surrounding country and supplies easy means of transportation. Population, estimated at about 500,000.

In September, 1896, Su-chow was opened by treaty as a place of foreign residence and trade.

SUCKER (from *suck*, AS. *sūcan*, *sūgan*, OHG. *sūgan*, Ger. *saugen*, to suck; connected with OIr. *sugim*, Lett. *sūkt*, OChurch Slav. *sūstai*, Lat. *sugere*, to suck). A fresh-water fish of the catfish family and belonging to the genus Catostomus and its allies, characterized by having the mouth inferior, and the lips thick and fleshy, the lower usually deeply divided. There are many species, all of moderate size and natives of the United States, except one in Siberia. Their general form is shown in the Plate of SUCKERS; in color they are dull, and with little tendency to markings, except that breeding males in most species acquire a rosy or orange lateral band. They inhabit rivers, lakes, and bayous, and obtain their food mostly by sucking up the mud and soft organic matter from the bottom. The most widely distributed species is the Northern or red sucker (*Catostomus catostomus*); the best known one, the common white sucker (*Catostomus Commersonii*), which is excessively abundant from Massachusetts to Kansas.

SUCKER STATE. Illinois. See STATES, POPULAR NAMES OF.

SUCKLING, Sir JOHN (1609-42). An English poet, born at Whitton, in Middlesex, where he was baptized February 10, 1609. His father, Sir John Suckling (knighted 1616), held high posts at the courts of King James and King Charles. In 1623 the poet entered Trinity College, Cambridge, but left without a degree. On the death of his father in 1627 he became heir to large estates. In 1628 he set out on extensive travels on the Continent and is said to have fought under Gustavus Adolphus. Returning to England in 1632, he soon became noted for wit, gallantry, and prodigality. Suckling took an active part in the plot to rescue Strafford from the Tower, and found it convenient to flee to the Continent. Impoverished and in despair, he seems to have poisoned himself in Paris in the summer of 1642. He was buried, says Aubrey, in the cemetery attached to the Protestant Church in Paris. Suckling's writings, few of which were published during his lifetime, were collected under the title *Fragmenta Aurea* (1646). The volume contains three plays, *Aglaura*, *The Goblins*, and *Brennoralt; Letters to Divers Eminent Personages;* a Socinian tract called *An Account of Religion by Reason;* and *Poems*. In a later edition (1658) appeared an unfinished tragedy, *The Sad One*. The fame of Suckling rests wholly upon his lyrics, inimitable for grace and gayety. Among the most beautiful are "Upon My Lord Brohall's Wedding," and the songs beginning "Why so pale and wan, fond lover?" and "I prithee send me back my heart." Consult *Selections*, with a memoir, by A. I. Suckling (1836; revised and enlarged by W. C. Hazlitt, London, 1874), and see the articles on the group of Cavalier or Court poets to which Suckling belongs: THOMAS CAREW; ROBERT HERRICK; and RICHARD LOVELACE.

SUCRE, sōō'krā. A department of Bolivia. See CHUQUISACA.

SUCRE. The official capital of the Republic of Bolivia, known also as Chuquisaca (Map: Bolivia, D 7). It is 8840 feet above the sea on a plateau of the Eastern Cordillera of the Andes, to the left of the upper valley of the Cachimayo, a branch of the Pilcomayo, and is 250 miles southeast of La Paz. It has the Supreme Tribunal of Justice. It contains the oldest university of South America, a fine cathedral, and the President's palace. Its industries are mining and agriculture, the latter being the more important; its population is about 26,000. Sucre was founded in 1536. The Spaniards first gave it the name La Plata, from the rich silver mines of the vicinity. Later as the seat of the *audiencia* of Charcas it served as the capital of Upper Peru. The city was the scene of the declaration of Bolivian independence from Spain, August 6, 1825, and later took the name of Sucre in honor of the Republic's first President. Though it has continued to be the official capital of Bolivia, the sessions of Congress, during the civil wars, have often been held at La Paz.

SUCRE, ANTONIO JOSÉ DE (1793-1830). A Venezuelan general, born at Cumaná, and educated at Caracas. He served in the various wars of independence in South America, from 1811 to 1824, was one of Bolivar's most valuable officers, and gained the victories of Pichincha (May 24, 1822), which freed Ecuador, and Ayacicho (December 9, 1824), which drove the Spaniards from Peru. He was elected first President of Bolivia in 1826, but resigned in 1828 to prevent a war with Peru, his resignation having been demanded by that country. The ex-President retired to Colombia, then at war with Peru, and gained for the Colombians the battle of Girón (February 26, 1829), which ended the war. He was elected President of the first Congress of the Republic of Colombia, and sent as commissioner to Venezuela. Upon his return from the Congress he was assassinated, it is supposed by political enemies, June 4, 1830.

SUCZAWA, sōō-chä'vä. A town of Bukowina, Austria, on the right bank of the Suczawa, 47 miles south of Czernowitz (Map: Austria, K 3).

The chief manufactures are linens, cottons, and fine leather goods; there are breweries, petroleum refineries, and potteries. The population, in 1900, was 10,946, of whom four-fifths were Germans.

SUDAMINA. See MILIARIA.

SUDAN, sōō-dän', or **SOUDAN.** A term now designating the vast region in Northern Africa lying between the Atlantic and the Red Sea, and between the Sahara Desert, on the north, and the Gulf of Guinea and the watersheds between Lake Chad and the Congo and between the Nile and the Congo, on the south. The northern line is about latitude 18° N., the southern about 4° N. The Sudan has been known as the 'Black Zone'—the home of the true negro race. The term is of somewhat confused signification both geographically and ethnically. Except Portuguese Guinea, Togo, and Kamerun, which belong to Germany, and the independent Liberia, all of the region of the Sudan is now virtually divided up between Great Britain and France. To Great Britain belong Gambia, Sierra Leone, the Gold Coast, Lagos, and Nigeria (both Northern and Southern); the government of the Egyptian Sudan (q.v.) is shared by England and Egypt; and Darfur is within the British sphere of influence. Under French control are Senegal, French Guinea, the Ivory Coast, Dahomey, French Congo, Bagirmi, and Wadai. The French Sudan (q.v.) was formerly the name of the territory in Western Africa lying between longitude 12° W. and Lake Chad and between the Sahara on the north and the countries (including Nigeria) along the north coast of the Gulf of Guinea. By the French decree of October 17, 1899, this region—generally known as West Sudan—was divided up. The western portion fell to Senegal, French Guinea, the Ivory Coast, and Dahomey. The remainder was formed into the three military territories of French Sudan (q.v.), the third of which reaches to Wadai on the extreme east. All the above French possessions, except French Congo, Bagirmi, and Wadai, are under a French Governor-General, whose seat is at Saint-Louis, Senegal. The third military territory above referred to connects on the southeast with French Congo, and thus forms the link uniting all the French possessions in Africa. This Governor-Generalship embraces also practically all of the Sahara (q.v.) in accordance with the French decree above named; for Great Britain has recognized the claims of France to all the region west of the Nile basin, thus embracing substantially all of the Sahara Desert (including the Libyan Desert).

For particulars as to topography, climate, commerce, races, etc., see articles on the different countries mentioned.

ETHNOLOGY. Within this broadest belt of Africa lying south of the Sahara, the following races and peoples are to be discriminated:

(1) *Semites*, consisting of Arabs, who under many names live in Kanem and Bornu about Lake Chad and eastward to Khartum and Kordofan.

(2) *Hamites*, whose main divisions are the Tibus, in many subdivisions, about Lake Chad; the Tuaregs, within the Niger bend and on the left bank of the Senegal; and the Fulah, Futa-Toro, and Futa-Jallon, scattered from Senegambia to Darfur and south to Adamawa.

(3) *Negroes*, who are divided into several groups. The west coast Negroes, including the Wolof, Serer, Sarakole, Toucouleur, Mandingo, Felup, and innumerable other tribes from the Senegal River to Sierra Leone; the Sierra Leone Negroes, comprising the Temne family and a multitude of pagan tribes; the Liberian Negroes, or Colonials, Kru, and many pagan tribes; the Ivory Coast Negroes, from Cape Palmas eastward, akin to the Kru; the Gold Coast Negroes, composed of the Tshi group, including the Fanti, Ashanti, and others, and the Ga groups, all pagans; the Slave Coast Negroes, making up the Ewe group, including the Dahomans (see DAHOMEY), and the Yoruba group; Niger Basin Negroes, including the Bambarra, Sonrhay, and Hausa (see HAUSA STATES); the Benue Negroes, composed of Moslem and pagan tribes in the region of the Benue River; the Lower Niger Negroes, or the Ibos (Niger delta), the Igbara (above the Benue confluence), and a multitude of pagan and Moslem tribes; the Chad Basin Negroes, comprising the Kanuris, the Baghirmi, the Mosgu, and many thousands of others chiefly pagan and mixed with Semites and Hamites; the Wadai Negroes, including the Maba and many other tribes all of more or less mixed blood, with a large percentage of Moslems; the Darfur and Kordofan Negroes, or Furs (Moslems), and Nuba (pagans); the Upper Nile Negroes, extending from Lake Victoria northward, and including the Madi, the Mittu, and a host of others, nearly all pagan; the Welle Negroes, comprising the Mombottu, the Momfu, the Niam Niam, the Akka, and a number of other tribes.

HISTORY. THE EGYPTIAN SUDAN. The Sudan has been apportioned by the events of the last few years into British and French spheres of influence. The Egyptian Sudan, now under British control, is practically coincident with the ancient Nubia (q.v.). It embraces the modern Egyptian mudirias, or provinces, of Khartum, Dongola, Berber, Kassala, Sennar, and Kordofan; and the muhafzas, or administrative districts, of Wadi Halfa, Suakim, and Fashoda. (See EGYPTIAN SUDAN.) The Eastern Sudan was brought under Egyptian control by Mehemet Ali (q.v.) in 1820-22 and so remained until in 1870 Ismail Pasha found it necessary to ask for assistance in restoring the waning authority of the Khedival government in the interior. The Englishman Sir Samuel Baker was made Governor-General of the Sudanese provinces and began their reduction and the suppression of the slave trade. He established his capital at Gondokoro, which he renamed Ismailia. Supposing that his work was accomplished, Baker returned to England. After his departure the slave trade was immediately revived and the administration of the provinces was intrusted to Charles George Gordon (q.v.), who with an able staff began the organization and development of this rich but little known region. Gordon continued his work in the face of all manner of discouragements and difficulties until his recall in 1879 upon the deposition of Ismail, and, though Gordon's organization was continued under his successor, Rauf Pasha,

there was a gradual reversion to earlier conditions. In 1882 the Sudanese tribesmen, for a long time restless under the greed and misgovernment of the Egyptian officials, took advantage of the difficulties in Lower Egypt and revolted. This, like the rising under Arabi Pasha (q.v.), with which it coincided in point of time, was primarily a revolt against foreign influence, but, unlike the latter, which was a political movement, it had its immediate origin in religious fanaticism. The incitement came from one of the alleged messiahs, known as mahdis (see MAHDI), who have been so common in Mohammedan countries. This man, Mohammed Ahmed, had some political genius and united the tribes in great numbers under his banner. For fifteen years he and his successor held the country under a religious and military tyranny. England had become so deeply involved in Egyptian affairs that she was compelled to take part in this struggle for the control of the Upper Nile country. A force of 11,000 English and Egyptian troops was dispatched to the Sudan under Hicks Pasha. This force was annihilated in a battle with the tribesmen at El-Obeid (November 3-4, 1883). England then determined to abandon the Sudan, but several posts were held by British garrisons and it was necessary to withdraw these troops. For this difficult task and for the settlement of the troubled affairs of the country, Gordon, because of his former success and his knowledge of the tribesmen, was given a new commission as Governor-General, and on February 18, 1884, he arrived at Khartum. In the meanwhile Osman Digna (q.v.) was making his power felt in the vicinity of Suakim, which became the scene of bloody fighting, Osman Digna being finally defeated (February-March, 1884). Gordon was surrounded at Khartum by the Mahdi's forces and cut off from all of his communications. After many delays, in part due to the fatal hesitation of the Gladstone Government, a relief force was sent out under Lord Wolseley, which after severe fighting arrived at Khartum, January 28, 1885. Two days before the city had been captured and Gordon killed. The English then retired and until 1894 gave up the attempt to reconquer the revolted provinces; but the growing British interest in East and Central Africa made it inevitable that England should seek to control a position of so great strategic importance. Upon the death of the Mahdi in 1885 his power passed to his chief lieutenant, the Khalifah Abdallah. In the interval of peace the Egyptian Army was reorganized and brought to an admirable state of discipline under its English officers, and in 1894, under the Sirdar, Sir Herbert Kitchener (q.v.), the struggle for the possession of the Sudan was resumed. This movement was stimulated by the threatened movement of Osman Digna (q.v.), the ablest Dervish leader, upon the Italian post at Kassala, where a victory might throw the Dervishes again upon the Egyptian frontier. After slow and patient preparation the advance up the Nile was made and Dongola was captured, September 23, 1896. Pushing forward his railway across the desert at the rate of about two miles a day, General Kitchener advanced steadily, always maintaining communication with his base on the Nile. The Khalifah was gradually hemmed in and on September 2, 1898, at Omdurman, opposite Khartum, he was defeated, his army annihilated, and his power completely broken. He himself was killed near Gedid in November, 1899.

The French had sent out a tentative expedition under Major Marchand (q.v.) to Fashoda, with a view to entering a wedge of French influence in the Eastern Sudan, but the French were themselves threatened by the tribesmen and were rescued by General Kitchener a few days after the victory at Omdurman. The aggressive attitude of England forced France to enter a diplomatic disclaimer. This led to the recognition by France in the supplementary treaty of 1899 of the English sphere of influence in the Sudan from Darfur and the Bahr-el-Ghazal eastward. By the Anglo-Egyptian convention signed January 19, 1899, the government of the Sudanese provinces was to be intrusted to a Governor-General appointed by the Egyptian Government with the approval of the British Government, the slave trade was prohibited, as well as the importation of arms and ammunition, and the British and Egyptian flags were to be used conjointly. The first Governor-General was General Kitchener. When he was called to South Africa, Col. Sir Reginald Wingate, his successor as Sirdar of the Egyptian Army, succeeded to the post.

FRENCH SUDAN. French exploration of the Sudan began in 1860, when Maze and Quintin penetrated east of Senegal as far as Segu Sikoro, which was again visited by Soleillet in 1878. The next year Bafoulabé was founded and a railway survey begun. The conquest of the country was begun in 1880 and pushed for fifteen years. Forts were erected, telegraph lines constructed, and acknowledgments of the French protectorate were gradually obtained from the native rulers. In 1894 Timbuktu was taken. On August 5, 1890, an Anglo-French agreement laid down the southern line of the French Sudan from Say on the Niger to Barrawa on Lake Chad. A further convention delimiting the French territory on the side of British Nigeria was framed June 14, 1898.

SUDERMANN, zōō'dĕr-män, HERMANN (1857—). A German dramatist and novelist, born at Matzicken, East Prussia, September 30, 1857. He studied history, philology, and literature at Königsberg and Berlin, and after some obscure years as tutor and journalist he won European and assured literary position by a drama [illegible] (1888), and the novel Frau

Sorge (1888; trans. as *Dame Care*, 1892). He followed these up with the novel *Der Katzensteg* (1889; trans. as *Regina*, 1898); the stories *Im Zwielicht* and a sensational drama, *Sodoms Ende* (1890); the humorous novel *Iolanthes Hochzeit* (1893); and his greatest drama, *Heimat* (1893; trans. as *Magda*, 1895); a fine novel of moral psychology, *Es war* (1894); an inferior drama, *Die Schmetterlingsschlacht* (1894); and *Das Glück im Winkel* (1896), a strong but unpleasant play. Then came three one-act dramatic scenes in verse collected under the appropriate title *Morituri* (1896); *Johannes* (1897), a realistic dramatic presentation of the story of John the Baptist; *Die drei Reiherfedern* (1898), an ethical and literary mystery in dramatic form. *Es lebe das Leben* (1902, translated *The Joy of Living*, 1902), is a powerful drama of the struggle between soul affinity and marital obligation. His work since 1894 shows failing power and has been much interrupted by sickness, but that for the six years preceding is, with the dramas of Hauptmann, the most significant in contemporary Germany, powerful in conception, admirable in technique, virile in its grasp of humanity in the more sombre aspects, and with occasional touches of delicate humor, though Sudermann is more skilled with the sterner weapons of satire. *Frau Sorge* is a pathetic Odyssey of duty with some romantic aberrations; *Katzensteg* is a declaration of 'naturalism;' *Iolanthes Hochzeit* breathes the serener realism of common life; *Es war* is a protest against the fruitlessness of brooding repentance. The dramas *Die Ehre*, *Sodoms Ende*, and *Heimat* are all social satires and militant democratic protests. By comparison the later dramas are increasingly out of touch with modern life. In *Die drei Reiherfedern* the evolution has become complete transformation. To some it seems a deepening, to others a sinking of his dramatic power. All Sudermann's greater works are translated into English. Consult: Brandes, *Menschen und Werke* (2d ed., Frankfort, 1895); Litzmann, *Das deutsche Drama* (Hamburg, 1896).

SUDETIC MOUNTAINS (Ger. *Sudeten*). A mountain system on the southwestern border of Silesia, Germany, which some of its ranges separate from Bohemia and Moravia (Map: Germany, G 3). It extends in a southeast direction from the water gap of the Elbe to the Moravian depression through which the Oder passes, and which separates the system from the Carpathian Mountains. The system is composed of a number of short, broken, more or less isolated and partly parallel ranges, consisting chiefly of crystalline slate, serpentine, and granite. These ranges inclose a number of large valleys. The best defined as well as the highest of the ranges, the Riesengebirge, lies near the centre of the system, and attains an average altitude of about 4000 feet, culminating in the Schneekoppe, 5266 feet above the sea. The higher ridges have an alpine flora, appearing above the large pine forests which cover the slopes. Many of the slopes afford fine pasturage and the foothills are well cultivated. The Sudetic Mountains are very rich in minerals, especially iron, zinc, lead, and copper, and in the southeastern portion there are large coal deposits.

ŚUDRA, shōō'drȧ (Skt. *śūdra;* possibly connected with Lith. *szúdas*, excrement). The name of the fourth caste of the Hindus. See CASTE.

ŚŪDRAKA (shōō'drȧ-kȧ). A Hindu king to whom tradition attributes the Sanskrit drama *Mricchakatika* (q.v.), which was probably composed in reality by Dandin (q.v.). The name Sudraka is not found in the history of India, and he seems to have been altogether mythical. He was, however, the centre of a number of legends, according to which he reigned either at Vidiśa, or Śobhavati, or Vardhamana. He is said to have been saved from death by a Brahman who killed himself to insure the king a life of a hundred years. According to another tradition he was the minister of a king named Śatavahana, who gave him half of his kingdom. Śudraka was the hero of two poems, the *Śūdrakakathā* of Ramila and Soimla, and the *Śūdrakavadha*, as well as of a drama, the *Vikrāntaśūdraka*, all of which have been lost. Consult Lévi, *Théâtre Indien* (Paris, 1890).

SUE, sụ, MARIE JOSEPH (known as EUGÈNE) (1804-57). A French novelist, born in Paris. He studied medicine, became an army surgeon, was transferred to the navy, cruised in the East, resigned in 1829, having inherited wealth, and gave himself successively to literature, dissipation, and socialistic agitation, writing *feuilletons* that rivaled those of Dumas in rapidity of production, fertility of imagination, and carelessness of execution. In 1831 he published *Plick et Plock*, the success of which led to *Atar-Gull* (1831), a novel of the sea, suggested by his own experience and by the American novels of Cooper. It revealed a gift of story-telling, but showed a reckless mingling of tragic and comic, pathetic and grotesque. Debts and disgust at his equivocal social position turned him into a socialist and convert to the propagandism of Fourier and Proudhon. His work in this spirit consists of long novels printed in cheap newspapers, but winning such hold on the masses and so swaying democratic opinion that the Government actually sought to check or divert his activity. As a critic of that day said, Sue was entering on an unexplored path when he began the *Mystères de Paris* (1842). As the novelist of the people he was undertaking to paint the sufferings, the needs, the possibilities of the working class with the intent of influencing their political action, and in doing this he won for the novel a new audience and a new interest. He entered on the task with an enthusiasm that fired his genius to the creation of types of character that still have power to horrify or charm. Both the *Mystères de Paris* and *Le Juif errant* (1844-45) were dramatized by Sue, and both have attained world-wide circulation. He wrote an *Histoire de la marine française* (1835-37) and two historical novels, *Latréaumont* (1837), and *Jean Cavalier* (1840). The later work of Sue is vast. He was elected to the Assembly in 1850, and was exiled in December, 1851. He died at Annecy in Savoy. Consult Mirecourt, *Eugène Sue* (Paris, 1858).

SUECA, swā'kȧ. A town of Spain, in the Province of Valencia, 23 miles south of the city of that name, on the left bank of the Júcar (Map: Spain, E 3). It is in a fertile valley. Population, in 1900, 14,422.

SUERA, swā'rȧ. A seaport of Morocco. See MOGADOR.

SUESS, sụs, EDUARD (1831—). An Austrian geologist. He was born in London, studied the natural sciences at Prague and Vienna, and from 1857 to 1891 was professor of geology at the University of Vienna. From 1873 to 1896 he was a member of the Austrian Lower House. In 1897 he became president of the Imperial Academy of Sciences. His more important contributions to geology, which have opened up a new path in geological inquiry, and laid the foundation for what is now frequently termed the 'new geology,' deal with the construction and relations of continents and mountain ranges, the dynamics of volcanoes and earthquakes, and the general movements of the earth's crust. His *Antlitz der Erde* (begun in 1885 and not yet completed) is a masterful exposition of the relations of the dominant features of the earth's surface, and the first luminous effort to correlate their multiform aspects and give to them their true geographic expression. His other works include: *Böhmische Graptolichten* (1852); *Brachiopoden der Kössener Schichten* (1854); *Brachiopoden der Kallstätter Schichten* (1855); *Ueber den Löss* (1860); *Die tertiären Landfaunen Mittelitaliens* (1871); *Die Entstehung der Alpen* (1875).

SUETONIUS TRANQUILLUS, GAIUS. A Roman historian, born probably a few years after the death of Nero. Pliny procured him the dignity of military tribune, which, by Suetonius's desire, was transferred to another. He was afterwards secretary of the Emperor Hadrian, whose favor he had secured. The date of his death is unknown, but it probably occurred about A.D. 160. All his works (among which, as we learn from Suidas, there were several on topics usually treated by grammarians) have been lost, except his Lives of the Cæsars, his Lives of Eminent Grammarians, and (in part only) his Lives of Eminent Rhetoricians. It is by the first of these works that he is most favorably known, containing information about the twelve Cæsars, from Julius Cæsar to Domitian, which is to be had nowhere else, and abounding with anecdotes which, while they too often prove the profligacy of his heroes, testify to the impartiality of their chronicler. The best editions are by Baumgarten-Crusius (Leipzig, 1816-18), Reifferscheid (ib., 1860), and Roth (ib., 1886). There are English translations of the Lives by Clark (London, 1732), and by Thomson and Forrester (ib., 1855).

SUEVI. The collective designation of a great number of Germanic peoples, as mentioned in Cæsar, *De Bello Gallico*, iv. 1. They occupied a district of indefinite extent on the eastern side of the Rhine, and may have been the same tribes as those subsequently known as Chatti, Longobardi, etc. Cæsar states that their territory comprised 100 cantons, and was densely wooded, that they had towns (*oppida*), but no strongholds, and that every year a part of the population left their homes to seek employment in war. The Suevi of whom Tacitus speaks (*Germania*, 38, etc.) seem to have dwelt north and east of the country of the Suevi of Cæsar, extending as far as the Elbe and the Baltic, which Tacitus calls the 'Suevic sea.' The peoples united under the rule of Maroboduus, the Marcomannic chief, were Suevic, and hence the Marcomanni and Quadi who figure in the reigns of Marcus Aurelius and Aurelian are often called Suevi. After the name had fallen into disuse as a collective designation, it reappeared in Ammianus Marcellinus, an historian of the third century A.D., as the name of a people occupying the same territory as the Suevi of Cæsar. We find them in alliance with the Burgundians, Alemanni, Alani, Vandals, etc. They are among the most notable of the barbaric peoples that broke up the Roman Empire in the northwest and west. Bursting through the passes of the Pyrenees (A.D. 409), they, along with the Vandals, overran and wasted Spain (q.v.). Those who remained at home in Germany seem to have spread during the fifth century east of the Neckar and the Raube Alb, and south as far as Switzerland. The mediæval Swabians were their direct descendants.

SUEZ, sōō-ĕz'. A town of Egypt, situated on the south coast of the Isthmus of Suez, at the northern extremity of the Gulf of that name, and near the southern terminus of the Suez Canal (Map: Egypt, F 3). It is built on a desert peninsula, and consists chiefly of unpretentious-looking houses. The European quarter, however, is regularly laid out, and contains the large warehouses of the Peninsular and Oriental Steamship Company. There are also a large English and a French hospital, and the town is supplied with water from a long distance through a fresh-water canal. To the south a large stone causeway, carrying a railroad, runs to the immense harbor of Port Ibrahim, at the entrance to the canal, 2 miles south of the town. Suez has railroad connection with Cairo and Ismailia, but its commerce is not very large, as only a small portion of the transit trade passing through the canal affects the town. Population, in 1882, 10,909; in 1897, 17,457. Previous to the discovery of the sea route to India around the Cape of Good Hope Suez was a flourishing emporium for the trade between Europe and the East. It subsequently fell into decay, and before the opening of the canal it was a wretched village of 1500 inhabitants.

SUEZ, GULF OF. One of the two arms in which the Red Sea terminates, and which inclose the Sinai Peninsula (Map: Egypt, F 3). It is the western and larger of the two, and its head is the extreme northern end of the Red Sea. It lies between the peninsula and the main portion of Egypt, and has an extreme length of 187 miles with a breadth of from 14 to 39 miles. It is artificially connected with the Mediterranean Sea by the Suez Canal.

SUEZ, ISTHMUS OF. The neck of land connecting Africa with Asia, and separating the Mediterranean from the Red Sea (Map: Africa, H 1). The shortest straight-line distance across it, between the site of the ancient Pelusium and the head of the Gulf of Suez, is 72 miles. The isthmus consists of a low, sandy, and stony desert, the lowest depressions being occupied by salt lakes and marshes, and it is almost wholly destitute of fresh water. A series of such depressions extends across the isthmus from the great coast lagoon in the north to the Gulf of Suez, and affords the route for the Suez Canal (q.v.).

SUEZ CANAL. A canal about 100 miles in length, which crosses the Isthmus of Suez and connects Port Said on the Mediterranean Sea with Port Thewfik on the Red Sea, by an artificial channel about 120 feet wide at the bottom, about twice as wide at the surface, and about 28 feet deep. In 1854 Ferdinand de Lesseps (q.v.) obtained permission from Said Pasha to form a company to construct a waterway from sea to sea without locks, and in 1855 an 'International Consultative Commission' selected from among the most celebrated civil engineers of Europe was appointed to report upon the scheme. The final report of this Commission was submitted to and accepted by the Viceroy in June, 1856. Its conclusions were in effect as follows: The system of indirect routes through the Delta of the Nile was rejected and a direct route through the isthmus from Suez to the Mediterranean was adopted. The dimensions of the channel were to be as follows: From the Red Sea to the Bitter Lakes, depth 26¼ feet, bottom width 210 feet, top width 320 feet; from the Bitter Lakes to the Mediterranean Sea, depth 26¼ feet, bottom width, 144 feet, top width 262 feet. At Port Said the plan of extending jetties directly seaward to protect the entrance was adopted. (See JETTY.) Basing his efforts on these conclusions, M. de Lesseps succeeded, in 1858, in forming a company, with a capital stock of £8,000,000, to build the canal.

TOPOGRAPHY. The construction of the canal was greatly facilitated by the existence along the route of four dried-up depressions which were formerly and have again become lakes of considerable area, namely, the two Bullah Lakes, the Great and Small Bitter Lakes, and Lake Timsah. (See Map of EGYPT.) These low-lying basins have an aggregate length of 27 miles. Excavation was required, however, through the Bullah Lakes, Lake Timsah, and the Small Bitter Lake, and also through a portion of the Great Bitter Lake. Consequently it was only for a length of eight miles of the Great Bitter Lake, where the natural depth exceeded that of the canal, that no excavation was necessary. The total distance from Port Said to Suez, Port Thewfik, is 88 nautical miles, or 100 English miles. The only serious obstacles to be overcome in the line of the canal were at El-Gisr, the summit of the work, situated between the Bullah Lakes and Lake Timsah, where the hills crossing the canal vary from 30 to 60 feet above sea-level over a length of 6 miles, and at the deep cutting of Serapeum, between Lake Timsah and the Great Bitter Lake. From Port Said to Kantara, a distance of 24 miles, the canal passes through Lake Manzaleh, a shallow lagoon which covers an area of nearly 1000 square miles. The soil encountered along the route was sand, sandy clay, and hard clay, with rare stretches of rock, and thus favorable to rapid and easy excavation. No serious engineering difficulties were presented by the harbor works at Port Said and Suez. In short, the canal works in general were of a very simple nature, but of vast magnitude, involving as originally proposed, the removal of 60,000,000 cubic meters of dry earth and 56,000,000 cubic meters of earth under water; and as they were situated in a country destitute of fresh water, a well-conceived organization was required to bring the colossal work to a successful issue.

PROGRESS OF THE WORK. Work on the canal was begun on April 25, 1859. The work progressed slowly at first, but the installation of a large fleet of dredges by means of which the dredged material carried by long and high projecting chutes was rapidly delivered on either bank of the canal at some distance from the slopes of the cuttings without the intervention of barges, and other mechanical appliances, had the effect of reducing by three-fourths the number of workmen needed to open the canal by the time originally estimated. More important than these, however, was the completion, in 1863, of a fresh-water canal and pipe line from Cairo by the way of Ismailia to Port Said. Financial difficulties were overcome, first, by decreasing the width of the bottom of the canal to 72 feet, and, second, by virtually increasing the capital of the company to £17,100,000. To compensate for the greatly reduced width of the canal, sidings were provided at every five or six miles between Port Said and Lake Timsah to allow vessels to bring up either for the purpose of passing each other or to moor for the night. In April, 1867, water from the Mediterranean was let into the marshy bed of Lake Timsah, and in March, 1869, it was allowed to flow into a near-by dry salt-incrusted basin of the Bitter Lakes. On November 17, 1869, the canal was opened to traffic with great pomp and ceremony. According to the expense account the canal had cost up to December 31, 1869, a sum of £16,632,953.

ENLARGEMENT OF THE CANAL. In 1883 it became evident that, owing to the great increase of traffic, a radical plan of improvement was demanded. In 1884, therefore, a second International Consultative Commission was appointed to consider the whole question and to report plans. This commission made its report in 1885, and shortly thereafter the enlargement works were begun according to the general plan recommended by the commission. The first stage of these enlargement works was completed in 1898; it consisted in an increase of the bottom width of the canal to 121½ feet, and of an increase of the navigable depth to 27 feet 10 inches. In addition to this uniform enlargement of section there were completed in 1899 nine new sidings, each 49 feet wide and 2460 feet long. In 1900 the average time of passage was 18 hours and 32 minutes for vessels navigating by night as well as day.

LIGHTING FOR NIGHT NAVIGATION. At the close of 1885 it was decided to make use of electric light in such a manner as to insure a safe passage by night through the canal, the company hoping in this way to diminish the traffic by day and thus to render the navigation less difficult until the full enlargement of the waterway was accomplished. After some experimenting with a system of landing marks, supplemented by Pintsch light buoys, it was decided that every vessel in motion during the night should itself be provided with the necessary apparatus to illuminate its passage through the canal. Accordingly it was arranged that every vessel passing by night should carry four lights, one astern, one on each side, and one ahead, to the last of which should be applied a powerful reflector capable of spreading light 4000 feet ahead of the vessel. The Mangin reflector is generally used. Men-of-war and large postal steamers carry their own apparatus. Smaller vessels

generally use portable apparatus which they hire upon entering and return upon leaving the canal. The effect of this system of lighting so as to permit night navigation has been virtually to double the carrying capacity of the canal.

TRAFFIC AND REVENUE. The toll charged for the passage of the canal was 10 francs per ton and 10 francs per passenger when the canal was first opened. Various changes were made in succeeding years, and in 1903 the toll was 8½ francs per net ton for loaded vessels, 7 francs for empty ships, and 10 francs per passenger. The accompanying table shows the traffic of the canal from 1869 to 1900, inclusive:

YEARS	Vessels	Gross tonnage	Net tonnage	Transit receipts
				Francs
1869	10	10,558	6,576	54,460
1870	486	654,915	436,609	5,159,327
1875	1,494	2,940,708	2,009,984	28,886,302
1880	2,026	4,344,520	3,057,422	39,840,484
1885	3,624	8,985,412	6,335,753	62,207,439
1890	3,389	9,749,129	6,890,094	66,984,000
1895	3,434	11,833,637	8,448,383	78,103,718
1900	3,441	13,699,238	9,738,157	90,623,608

In 1899, according to the United States Consular Reports, the tonnage passing the canal was 9,893,022, and the revenue was $17,510,142; in 1900 the corresponding figures were 9,738,152 tons and $17,480,356.

HISTORY. The plan of a water connection between the Mediterranean and the Red Sea goes back to early Egyptian history. Such a canal seems to have been constructed in the reigns of Seti I. and Rameses II. (about B.C. 1350-1300), extending from the Nile to Lake Timsah and thence to the Red Sea. When this had been choked up by the sands in the course of ages, a new canal was begun by Necho, a son of Psammetichus I. (about B.C. 600), between Bubastis on the Nile and the Red Sea, but was left unfinished till the time of Darius Hystaspis (B.C. 521-486), who completed the work. About the beginning of the Christian Era the canal was no longer navigable, but it was probably restored under Trajan. The last restoration was made in the seventh century by Amru, the Mohammedan conqueror of Egypt, who connected Cairo with the Red Sea. During Napoleon's invasion of Egypt (1798-99) the project of piercing the isthmus was carried to the extent of preliminary surveys being made, but, owing to a miscalculation on the part of the engineers which seemed greatly to enhance the difficulties of the work, the execution of the plan was delayed till the French were forced to abandon Egypt. An international commission of engineers made a preliminary survey in 1846 to ascertain the practicability of a level-water canal. The English engineer on the commission, George Stephenson, strongly opposed a canal and recommended to his Government a railroad from Cairo to Suez, and this was constructed by British capital in 1858. By the terms of the De Lesseps concession (see above) the canal was to be constructed without expense to Egypt, which was to receive 15 per cent. of the gross receipts for ninety-nine years, at the expiration of which period the canal was to revert to the Egyptian Government. When, however, De Lesseps found it impossible to enlist the large amount of capital necessary, he turned to Said Pasha, secured from him a large loan for preliminary work and promoting, and later a subscription for nearly half of the stock, which was about £17,000,000. Said was not able to pay his subscription and his warrants had to be cashed in London. The Egyptian Government had agreed to furnish labor at a nominal price, the fellaheen to be well treated and their health to be cared for. The violation of the latter condition on the part of the canal company aroused a protest in the name of humanity, especially from England, which had never looked with favor on the canal and suggested to the Sultan that the work be stopped. His approval of the concession, as suzerain, which had been provided for in the original contract with Egypt, had never been obtained. He now approved the concession, but decided that the fellaheen must not be forced to do the work. The company complained of the Egyptian Government's compliance with this order from Constantinople as a breach of contract, made heavy claims for damages, induced the Khedive to accept Napoleon III. as arbitrator, and on this and a later claim wrung from the exhausted resources of Egypt over eighty million francs. The direct and indirect cost of the canal to Egypt is estimated at about $85,000,000. In 1875 Ismail Pasha (q.v.) appealed to Europe for aid in his financial difficulties. Among other measures that were taken was the sale of his canal stock to England, 176,602 shares, for £4,000,000. This made England, which had originally opposed the canal project, the heaviest owner in it, and combined with the general financial assistance rendered to Egypt gave that power a direct interest in Egyptian affairs. A very short time sufficed to show that the canal was of the utmost value as the passageway between England and her Oriental possessions. England and France at first exercised together that tutelage over Egypt which the financial situation rendered necessary. Later events led England to assume this responsibility alone. The Suez Canal was the key to this political development, as it has become in part to the complicated situation in the near East. See EASTERN QUESTION; EGYPT.

SUFFOLK, sŭf'ok. A southeastern maritime county of England, bounded on the east by the North Sea, on the north by Norfolk, and on the south by Essex (Map: England, G 4). Area, 1489 square miles. Population, in 1891, 371,235; in 1901, 384,198. The surface is for the most part flat, falling away into marshes on the northwestern and northeastern borders. The tributaries of the Waveney and of the Stour, together with the river Lark, an affluent of the Great Ouse, and the Gipping, with its estuary, the Orwell, are the chief streams. The soil is of various kinds, some of which are very productive for the ordinary crops. Capital, Ipswich.

SUFFOLK. A town and the county-seat of Nansemond County, Va., 22 miles southwest of Norfolk; on the Nansemond River, and on the Norfolk and Western, the Seaboard Air Line, the Southern, the Atlantic Coast Line, and the Suffolk and Carolina railroads (Map: Virginia, H 5). It is an important railroad centre, and one of the largest peanut-cleaning markets in the State. There are car works, a stove foundry, various wood-working mills, iron works, hosiery mills, and brick plants. The surrounding region is fertile and is well adapted to farming. Population, in 1890, 3354; in 1900, 3827.

SUFFOLK, EARLS AND DUKES OF. Dignities held by several noted English families. The title Earl of Suffolk was conferred on ROBERT DE UFFORD (1298-1369), who held high office under Edward III. He was made admiral of the northern fleet in 1344, fought at Crécy and Poitiers and was repeatedly intrusted with diplomatic missions. He was succeeded by his son WILLIAM DE UFFORD, who was one of the most popular statesmen of the later part of Edward III.'s reign, took a share in the suppression of the peasant revolt of 1381, and died in 1382, leaving no male heirs. A new line of Suffolk was founded by MICHAEL DE LA POLE (1335?-89), who fought in the French wars, became in 1376 admiral of the northern fleet, negotiated the marriage of the young Richard II. with Anne of Bohemia, and in 1383 was made chancellor. By marriage he acquired extensive possessions in Suffolk and these were added to by royal grants. In 1385 he was created Earl of Suffolk. His rapid elevation and the great influence which he exercised over the King aroused the hostility of the nobles and in 1386 he was dismissed from office on the demand of Parliament, which proceeded to impeach him of treason and malfeasance. The King's favor could not protect him and in 1387 he fled the country. In his absence he was condemned to be hanged. He died at Paris. His son MICHAEL DE LA POLE (1361-1415) was restored to his father's dignities in 1397 and fell at Harfleur in 1415. He was followed by his eldest son, who was killed soon after at Agincourt, being succeeded by his younger brother WILLIAM DE LA POLE (1396-1450), best known of all that have borne the title. He served in the French wars under Henry V., the Duke of Bedford, and the Earl of Salisbury, upon whose death in 1428 he became head of the English forces in France. He failed to capture Orleans, which was relieved by Joan of Arc in 1429, and in the same year was taken prisoner. Ransomed at a heavy cost he took little part in military affairs, but for twenty years played a most important rôle in the government. As a member of the King's council he sought to bring about peace with France and was one of the English representatives at the abortive congress of Arras in 1435. The death of the Duke of Bedford in the same year left him one of the two most powerful men in the kingdom, his great rival being Humphrey Duke of Gloucester, uncle of the young Henry VI. In 1448 Suffolk was at the head of an embassy which arranged a truce with France and brought about the marriage of Henry VI. with Margaret of Anjou. This alliance gained him tremendous though temporary popularity. The government fell entirely into his hands and after the death of Gloucester in 1447 he was master in the kingdom. He became in rapid succession chamberlain, lord warden of the Cinque Ports, admiral, governor of Calais, and Duke of Suffolk. He was hated, however, by a large faction of the nobility, at whose head stood Richard, Duke of York. He lost his popularity owing to the surrender of Anjou and Maine, to which he had assented as one of the conditions of the King's marriage, and the feeling of hostility was intensified by the renewal of war with France in 1449, in the course of which Normandy was lost to the English. Popular opinion accused him also of having encompassed the death of the 'good Duke Humphrey.' In 1450 the Commons accused him of having betrayed the King to the French and brought articles of impeachment against him. The King whose favor he never lost senteneed Suffolk to five years' exile. On May 1, 1450, the Duke set sail for France, but the ship on which he embarked was intercepted by a royal man-of-war, Suffolk was compelled to go on board, and on the following day was taken into a small boat and beheaded. His body was cast upon the beach at Dover. The sanguinary deed was probably due to Richard of York, his mortal enemy.—JOHN DE LA POLE (1442-91) second Duke of Suffolk, only son of the preceding, regained the ducal title in 1455. He joined the York party, married a sister of Edward IV., and was in favor under the rulers of that family and under Henry VII. His eldest son John took part in Lambert Simnel's rebellion and fell at Stoke in 1487. He was attainted and the greater portion of the family estates was lost.—EDMUND DE LA POLE, a younger brother, received a part of the confiscated estates with the title of earl. He plotted to seize the throne with the aid of German troops but the plan miscarried and he fell into the hands of Henry VII., who, however, spared his life and sent him to the Tower. He was beheaded with his brother Richard in 1513, and left no male issue. The title Duke of Suffolk was subsequently borne by CHARLES BRANDON (died 1545), the favorite of Henry VIII. and husband of his sister Mary Tudor. He was succeeded by his two young sons, who died in 1551, on the same day.—HENRY GREY, third Marquis of Dorset, who had married a daughter of Charles Brandon, was next made Duke of Suffolk. He was the father of the unhappy Lady Jane Grey (q.v.). In 1553 he attempted to raise the north, was betrayed and beheaded. In 1603 THOMAS HOWARD, second son of Thomas, fourth Duke of Norfolk, was created Earl of Suffolk. His second son was created Earl of Berkshire in 1626 and in 1645 the two titles merged. The present bearer of the title is Henry, 19th Earl of Suffolk and Berkshire, born in 1877.

SUFFRAGAN (ML. *suffraganus, sufraganus*, from Lat. *suffragari*, to assist, to vote for, from *suffragium*, vote, originally probably a broken potsherd used in voting, from *suffringere, subfringere*, to break, from *sub*, under + *frangere*, to break). The name given to a bishop to express his relation, in a province, to the archbishop or metropolitan (q.v.). The name is also applied to coadjutor or assistant bishops, especially in the Church of England, where suffragan bishops are usually known by territorial titles, although they have no independent jurisdiction, and their local commission, given by the bishop of the diocese, terminates with his death. In the Roman Catholic Church similar assistant bishops are usually designated by the titles of extinct sees. See TITULAR BISHOPS.

SUFFRAGE (Lat. *suffragium*, vote). In a representative government, the act of a qualified voter in participating in the choice of government officials or in voting on laws or constitutions submitted to the electorate. There are two views as to the basis of suffrage. One holds that it is a privilege bestowed by the State upon such of its citizens as are capable of exercising it intelligently and for the public welfare. The other

view regards it as the natural right of all adult male citizens. This was the doctrine of the eighteenth-century philosophy, but has been rejected by most States, suffrage having been restricted by them on some of the following bases: ownership of property, payment of taxes, educational attainments, moral character, residence, religious profession, etc. An almost universal rule has been to exclude women, children, lunatics, idiots, convicted criminals, and aliens from the exercise of the suffrage, although there have been and are still exceptions.

In the American colonies the qualifications for suffrage varied greatly. Thus in Virginia the suffrage was restricted to 'freeholders and housekeepers;' in Massachusetts until 1664 it was restricted to church members; in the New Haven Colony it was the same; under the Massachusetts charter of 1692 it was restricted to freeholders of a certain amount of property. The religious tests were the first to be abolished, the last survival of the kind existing in South Carolina from 1778 to 1790. The right of each State to regulate the whole matter of the suffrage within its limits was recognized by the Federal Constitution and in hardly any two States were the requirements the same. During the early part of the nineteenth century a freehold qualification was required in Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Virginia, Maryland, North Carolina, and South Carolina, the amount ranging from £20 in New York to £60 in Massachusetts or from 25 acres of improved land in Virginia to 50 acres in Maryland and South Carolina. The payment of taxes alone was required in Pennsylvania, Delaware, and Georgia. During the first three decades of the nineteenth century the freehold requirement was abolished in nearly every State. Likewise the tax and ownership of personalty qualifications disappeared in most of the States, so that adult male suffrage became the general rule long before the outbreak of the Civil War. Free negroes were almost everywhere excluded.

A readjustment of the suffrage followed the Civil War. The Reconstruction Acts of 1867 conferred the right of suffrage on the freedmen. In all the States that had rebelled the negroes voted for the first time in 1867 in the elections for delegates to the reconstruction constitutional conventions, and in the following year on the question of adopting or rejecting the new constitutions. The States having once been readmitted to the Union, however, there was nothing to prevent them from withdrawing the right temporarily bestowed on the freedmen by Congress. The Fourteenth Amendment was intended to guard against such action on the part of the reconstructed States. On account of the difficulty of enforcing this amendment and the inadequacy of protection which it afforded the negro population, the reconstructionists advanced another step. In the first place, it was made a condition precedent to the readmission to the Union of the remaining unreconstructed States that they adopt constitutions with unamendable provisions guaranteeing the right of suffrage to negroes. At the same time the Fifteenth Amendment to the Federal Constitution was carried. But the Constitution confers the right of suffrage directly on no one, so that there are no United States voters. This is a prerogative of the individual States, and they may exclude any number of persons on other grounds than race or color, such as illiteracy, lack of citizenship, non-payment of taxes, etc., subject to the penalty of a reduction of representation in Congress.

The attainment of the twenty-first year of age is a qualification in every State. In a number of States women are allowed to vote in school elections and in several Western States they vote in State elections. The States may and generally do require voters to register within certain periods as a means of preventing frauds at the election, and this requirement indirectly excludes some. Residence within the State and district for a certain period previous to the election is an almost universal requirement. Educational tests have long existed in Massachusetts and Connecticut and have been introduced in a number of the Southern States, as a result of which the suffrage has been practically restricted to the whites in Mississippi, South Carolina, Louisiana, North Carolina, Alabama, and Virginia. In Louisiana and North Carolina the hereditary principle has also been introduced into the suffrage by the so-called 'grandfather' provision, which extends the right to vote to all adult males, without regard to intelligence or property, whose fathers or grandfathers possessed the right to vote on January 1, 1867. See the sections on government of the various countries and States for suffrage requirements.

SUFFREN DE SAINT-TROPÈZ, sụ'frăn' de săn trō'pā', PIERRE ANDRÉ DE (1726-88). A French naval hero, born at Saint-Cannat, near Lambesc. He was captured by Hawke in 1747 and after his exchange served for years with the Knights Hospitalers of Malta. From 1767 to 1771 he was again in the service of Malta. He was created Baillie in the order of the Knights, and was thereafter popularly known as the Baillie de Suffren. In 1772 he was commissioned captain in the French Navy. His most noteworthy services were rendered at the very close of his career, against the English, in the Indian Ocean, where he went in command of a squadron in 1781.

SUFIISM, sōō'fē-iz'm (from Ar. *sūfi*, mystic, clad in woolen, from *ṣūf*, wool; less plausibly derived from Gk. *σοφός*, *sophos*, wise). A coherent and organized system of Mohammedan mysticism.

Formerly Sufis were called *Urafa*, 'Gnostics' or 'theosophists.' To-day the most common name is Fakirs, or Dervishes, 'the poor,' but it must be understood that not all the poor in Persia, Egypt, or Turkey, the main homes of Suflism, are Dervishes, and that not all who are called or pretend to be Dervishes are Sufis. Aship Pasha (A.D. 1332) aptly said: "He who forsakes the world is a Dervish; he whom the world forsakes is a beggar."

The origin of Suflism is disputed. Some Sufis say that "The seeds of Suflism were sown in the time of Adam, germed in that of Nuh (Noah), budded in that of Ibrahim (Abraham), and began to develop in the time of Musa (Moses); reached maturity in Isa (Jesus), and produced pure wine in Mohammed." The word Suflism seems to have been first adopted by Abu Hashim, a Syrian (A.D. 780). Abul Said Abul Khair (about 820) is mentioned as founder, while Al-Ushairi (1073) states that the name was in common use about 815. Mythical tales give

the origin to Rabia al Adawiyya (752), a pious woman much spoken of in Sufiism. There seems to be historic evidence to prove that, in spite of Mohammed's precautions against mysticism, it originated with his favorite Ali. Those who maintain that Sufiism has its origin in the Vedanta (q.v.) place it, of course, much further back in time. Despite certain analogues, as the Persian *pir*, or sage, who corresponds to the *guru*, or teacher, of India, who initiates the neophyte into the esoteric mysteries, there are many fundamental differences between the two systems. Max Müller (Gifford Lectures of 1892), who only knew Sufiism second hand, derives it from the Vedanta and quotes Sir William Jones, who knew less than himself, on its principal doctrines. Both overlook the fundamental difference between the two. Sufiism is radically theistic and seldom swerves far from the Koran's intense belief in the One. The Vedanta is pantheistic with occasional theistic phraseology. The Sufiis are so strongly devoted to the Beloved (viz. God) that they look for Divinity everywhere and see Divinity anywhere; the superficial observer therefore easily comes to regard the Sufis' love pantheistically, and compares it with the Vedantic doctrine of absolute pantheism, summed up in the phrase *tat tvam asi*, 'That (the Universal Spirit) thou art.' It may, however, be admitted that later Sufiism shows forms of expression very similar to Vedanta, but also that no historic connection has been proved. It cannot be denied that the intellectual forms given to most of the Sufi doctrines in Persia are from foreign sources. Among historic forces which thus have molded Sufiism must be mentioned especially the Peripatetic philosophy, Neo-Platonism, and Zoroastrianism. The latter's formalism lent itself admirably to the Arabic intellect, and its doctrines of Light harmonized well with Sufiistic ascetic notions of the One. From Greek sources came dialectics and cosmological notions. The latter, though common in Sufiism, are alien to its primitive nature. The Greek influence is traceable to the philosophers Diogenes, Hermias, Eulalias, Priscian, Damascius, Isidore, and Simplicius, whom Justinian's intolerance drove into exile and who came to Nushirwan's court. The rich symbolism of Sufiism is either of Zoroastrian origin or indigenous, except its Alexander legends.

A few really great Sufis lived before the close of the second century of the Hejira (815). Among them and those immediately after are to be mentioned the Egyptian Dhun-Nun (859), who introduced the doctrine of ecstasy and mystical stages; Sirri Sagvati (867), who introduced unification; Junaid (910), who reduced Sufiism to writing; and Al-Nallaj, who became famous because he went about crying "I am the true One," for which he was put to death by torture (921). The *Fihrist* (987) represents him as a 'wily conjurer,' but Sufis consider his death the result of the workings of the occult law which brings death upon him who divulges divine secrets. Ghazali (q.v.) (d. 1111) and Jalal-ud-Din Rumi (q.v.) (d. 1273) were the two most famous Doctors in Sufiism. Omar Khayyam (d. 1123), reckoned by some as a Sufi, became known to the West through Fitz-Gerald's brilliant quatrains. Nizami (q.v.), Farid-ud-Din Attar (q.v.), Sadi (q.v.), Shamsi, Hafiz (q.v.), Anvari, Jami (q.v.), and Hatifi (q.v.) are sub-poets of renown. Jami (d. 1492) has been called the last Sufi, and with some justice. After him Sufiism slowly declined, but the nineteenth century saw its powerful revival in Turkey, though its Turkish representative names are almost unknown outside of Turkey. From Turkey and Egypt comes what may be called a Neo-Sufiism.

Primitive Sufiism is not doctrinal; it is an 'experience,' a 'feeling of God,' a 'mystery of godliness,' and does not primarily have anything to do with the notions of the intellect. Within two hundred years from its origin, however, it assumed doctrinal forms and it remained settled in them, though it never gave up the main characteristics of its beginning. The two chief doctrines of Sufiism are that of the One (*Ahad*) and that of 'the Way to the One' (*tariqat*). A Sufi first of all endeavors to realize that 'the One' is the only existence, that there is not only 'no god but God,' but that there is nothing but God. Next, he enters upon 'the journey to the rose-garden of Union.' The Sufi's belief is not pantheism in the Greek sense; he does not 'make everything God except God himself;' on the contrary, everything is naught except Divinity and it is Divinity that gives life to the dead Non-Being. The world is a phantasmagory, and the time will come when it shall pass away. God's reason for creating the world is found in this saying: "I was a Hidden Treasure and I wished to be known, so I created Creation that I might be known." The form of creation is not only truth and goodness, but also and essentially beauty. Sufis lay more stress upon the conception of Divinity as beauty than other mystics or religions.

The Sufi 'way to God' is similar to the well-known ideas on that subject among Western mystics. With the help of a guide, 'the traveler' ascends step by step to union with God or through awakening to regeneration and sanctification to union. The 'Way' is ascetic and full of occult practices, such as dances, silences, etc. All men may reach union. Every man is essentially both a *microtheos* and a *microcosmos*, or, as Shamsi of Tabriz sings in echo of numerous other Sufis: "My place is in the Placeless; my trace is in the Traceless." "I gazed into my own heart; there I saw One."

Sufi symbolism is a mystery and permeates the entire system of Sufiism. A symbol to a Sufi is not merely an object which stands for some other object or idea. For him every object has besides its own immediate signification also an ideal content, and it is this latter which is the real object of the Sufi's search. He finds it by means of Love (*isq*). The object is to the ecstatic a vivid, instantaneous revelation of the inscrutable. Objects are therefore 'veils,' not veils that hide, but 'veils' that reveal the One. All Sufi poetry is written with a double sense and the initiates can read five others besides. The now comparatively well-known ghazels of Hafiz, Sadi, Jami, and others abound in 'veils,' which the Occidental calls voluptuous and bacchanalian, but to the Sufi, Oriental as he is, they are not low or degraded, but simply descriptive of emotions or soul-life. As such they suggest to him deeper and more universal states of life. The *embrace* means discovery of the mysteries of Godhead; *wine* divine love and wisdom; a *tavern*

signifies what we call a church, because through the rapture of the wine and the wonder of the embrace the Sufi is filled with thoughts of the Beloved; a *red rose* is the beloved damsel and the *nightingale* is the lover; but the Beloved is always God.

There are many sects among the Sufis, but their differences are not strictly Sufiistic; they have arisen on external and unessential ground and are of little interest outside of Sufiism. Sufiism has exerted a powerful influence where Mohammedanism rules, especially in Arabia, Persia, and Egypt, and it is flourishing to-day in Turkey. India also has a large number of Sufis. Persian literature, more than any other, bears strong impress of it.

SUGAR, Manufacture of. Cane sugar is found in varying quantities in many plants, but sugar-cane (*Saccharum officinarum*), the sugar beet (*Beta vulgaris*), the sugar maple (*Acer saccharinum*), and various species of palms are its only commercially important sources. (See table.) At one time the United States Department of Agriculture experimented with sorghum (*Sorghum vulgare*), which seemed a promising source of cane sugar, but though several varieties containing from 10 to 20 per cent. of cane sugar were produced by seed selection, sorghum has never been more than locally important as a source of syrup, because great difficulty has been experienced in purifying the juice by any known process except that recommended by the department, a process which failed to attract investors, because alcohol, its principal factor, was subject to unfavorable revenue regulations. Several sorghum sugar factories were erected in Kansas and elsewhere about 1890, but development failed to pass the experimental stage. In 1889 the production of syrup was 24,235,219 gallons; in 1899, 16,972,783 gallons. (See Sorghum.) Experimentally, small quantities of cane sugar have been made from corn stalks and from melons. Owing to the presence of impurities, including saccharine substances other than cane sugar, raw sugars obtained from the various plants mentioned differ greatly in flavor, but, contrary to popular belief, the granulated or refined sugar derived from them differs not at all in sweetening power, since it consists of more than 99 per cent. of cane sugar and less than 1 per cent. of impurities including mineral matter, water, etc.

Cane Sugar. During the middle of the eighteenth century sugar-cane (q.v.) was introduced from Southern Europe into Louisiana, where the successful manufacture of sugar began during the last decade of that century. Formerly the juice obtained by more or less crude processes was evaporated in open pans ('kettles') and the molasses allowed to drain in barrels or other forms of coolers. The molasses, which was generally not reboiled, was superior in flavor and lighter in color than that remaining after the removal of several crops of crystals in a modern sugar factory, because of its smaller proportion of impurities.

The modern sugar factory is equipped with every apparatus suggested by scientific research. The juice of the cane is extracted in 'mills' consisting mainly of a system of rollers, often eight, arranged in three sets, through which the cane successively passes; first, two corrugated rolls, which break and prepare the cane for the heavier pressures applied by the succeeding sets of three rolls each. Between the second and third set the crushed cane is sprayed with water to facilitate the removal of sugar by the last set. This process removes from 50 to 85 per cent. of the sugar, according to the efficiency of the apparatus and the care with which it is operated. The crushed cane, called 'bagasse,' is used for fuel to furnish steam for the engines and pumps, and for the evaporation of the juice. The diffusion process, which is used in relatively few cane-sugar factories (see *Beet Sugar*), secures from 90 to 97 per cent. of the sugar, but the bagasse is unfit for fuel.

Aside from the minor details the process of manufacture is essentially the same in each case. For white sugar the juice is bleached with the fumes of burning sulphur. Lime is next added to neutralize it or to leave it faintly acid. In the subsequent heating the insoluble compounds of lime formed with the organic acids, the albuminous bodies, and other impurities rise to the surface and are removed by skimming or are precipitated. Since the quality of the sugar produced depends upon this process of clarification, considerable skill and care are bestowed upon it. The skimmings and stillings, which were formerly thrown away, are now filtered and saved, and in many factories the clear juice is often filtered also to remove all traces of insoluble matter.

In a new and efficient process adopted by many factories during the closing decade of the last century the limed juice is pumped continuously under high pressure through pipes surrounded by steam in a chamber ('superheater'); thence it passes through a cooler in which the same pipes, extended, are surrounded by the cold juice, which absorbs the surplus heat; and lastly it passes direct to the filter presses and settling

tanks. The process is continuous, accomplishes a high degree of purification, eliminates the labor of skimming, and is conducted in a closed apparatus.

The clarified juice containing from 10 to 18 per cent. of sugar is evaporated in multiple-effect vacuum evaporators, so called because the heating effect of the steam is utilized in vacuo as many times as there are pans in the series, steam being applied to the first pan and the vapor from the boiling juice to the second pan, and so on. From the last pan the vapor passes to a condenser, kept in constant vacuum by a continuously acting pump from which it flows away. The juice is pumped continuously through the pans, from the last of which it issues as a syrup containing about 50 per cent. of dissolved matter, including from 40 to 45 per cent. of sugar and 5 to 10 per cent. of impurities.

The syrup is then admitted to the 'strike' pan, a cylindrical cast-iron vessel provided with a vacuum pump, condenser, and several coils of copper tubing, to which steam may be admitted as desired. After further condensation, and when about one-fourth or one-third full of thick liquor, a fresh charge of cool syrup is admitted to cause the formation of minute sugar crystals ('grain'), the size of which can be controlled by the sugar-boiler, who regulates the boiling and the admission of fresh syrup so as to avoid the formation of new crystals, 'false grain.' The pan is emptied when it becomes filled with a dense mass of sugar crystals and syrup, 'massecuite,' which is conveyed to cylindrical metal vessels (centrifugal machines) with perforated walls and supported upon vertical shafts making from 1000 to 1500 revolutions a minute, the force throwing the syrup out through the walls. After the sugar is sprayed with water in which a little ultramarine or other harmless blue is added to correct the yellow tint, it is removed, and in the case of granulated sugar is dried in revolving drums (granulators) through which a current of warm air passes.

The molasses may be reboiled even three times for a 'second,' 'third,' and, if exceptionally pure, even a 'fourth' sugar. In these cases the massecuites, which contain no crystals when they leave the vacuum pan, are placed in 'sugar wagons,' tanks or metal boxes on wheels, for a few hours or days until crystals form. These second and third massecuites are frequently granulated in cylindrical 'crystallizers' while constantly stirred by revolving paddles, a method ('crystallization in movement') very generally adopted in modern beet-sugar factories.

BEET SUGAR. The manufacture of sugar from beet roots is a comparatively modern industry, having its inception in the investigations of Margraff, who in 1747 announced to the Berlin Academy of Sciences the analyses of several sugar-containing plants and predicted that the sugar beet (q.v.), being the most saccharine of the plants examined, would become the basis of a great industry. Nearly half a century later the problem was solved by a pupil of Margraff, Achard, who made a considerable quantity of beet sugar and announced his methods to the Berlin Academy of Sciences and to the Institute of France in 1797 and 1799, respectively. In Germany several beet-sugar factories were built within the next decade, and beginning with 1810 the industry, being stimulated by governmental aid in both countries, developed steadily. Astonishing improvements have been wrought in all branches. The percentage of sugar in the roots has been increased by selection from less than 7 per cent. at the beginning to an average in 1900 exceeding 14 per cent. and a maximum of more than 20 per cent.; the quality of the roots, the yield in tons per acre, and the improved processes of manufacture, which according to German statistics have reduced the weight of roots necessary to yield a pound of sugar from 18 pounds in 1837 to 7.02 pounds in 1899, have combined to make the industry profitable both in Europe, with its cheap labor, and in America, with its cheap lands.

In the manufacture of beet sugar the roots, already trimmed of leaves, are conveyed by water in little canals which extend through the bottoms of the V-shaped storage sheds, to the washing machine, where every particle of soil is removed by revolving brushes, the roots constantly progressing against a current of water toward the automatic weighing machine. After the weight has been recorded the roots go to the slicer. Here they are cut by corrugated knives into little V-shaped slices (cossettes) that drop into large iron tanks (cells), a series of 12 to 14 of which constitute a 'diffusion battery,' so called because the sugar is removed from the cossettes by water into which the sugar diffuses and which passes by a complicated system of pipes and valves through all the charged cells of the series, always from the longest filled cell, containing nearly exhausted cossettes, to the most recently filled, thus removing the largest possible quantity of sugar with the smallest quantity of water. One of the two uncharged cells is always being filled with fresh cossettes, the other being emptied, its cossettes containing less than 0.5 per cent. of sugar. Thus the process is continuous. The exhausted cossettes, which are used as stock food, are pressed to remove the excess of water and in some cases are dried to enhance their transporting and storing qualities.

NUMBER AND NOMINAL DAILY CAPACITY OF ESTABLISHMENTS IN 1900, 1899, AND 1889

[From the Twelfth Census]

STATES AND TERRITORIES	1900		1899		1889	
	Number of establishments	Nominal daily capacity in tons of beets	Number of establishments	Nominal daily capacity in tons of beets	Number of establishments	Nominal daily capacity in tons of beets
The United States	37*	22,310	31†	19,110	15	7,560

* Includes two idle establishments. † Includes one idle establishment. ‡ Includes two auxiliary factories. § Includes one auxiliary factory at which no sugar is manufactured, but juice is extracted from the beets and pumped to a central factory for treatment. In November, 1903, other factories not mentioned in the above table were opened as follows: Michigan, 6; Utah, 2; Colorado, 1.

When the 'diffusion juice' leaves the battery the coarse particles of beet pulp are filtered out and from two to three pounds of lime added for each hundred pounds of beets used. Carbon dioxide is then forced through the liquid to precipitate the lime, together with certain impurities, after the removal of which the operations of liming, carbonizing, and filtering are repeated. If the final product is to be a white sugar, the clear juice is then bleached with sulphurous acid and again filtered. The subsequent treatment corresponds more or less closely with that employed in the factories using sugar-cane.

The United States Department of Agriculture and various experiment stations, by means of special appropriations, have assisted greatly in the development of the beet-sugar industry, which is established on a firm footing in America. Especially since 1897 (see table) has the growth been rapid, the capital invested being, in 1900, more than $25,000,000.

Maple Sugar. The manufacture of maple sugar is carried on more or less wherever sugar-maple trees are abundant, especially in the Northern Atlantic and Northern Central States, the leading producers, according to census returns, being Vermont and New York. In some cases the natural groves have been extended by planting. The busy period depends upon the locality and upon the season, sometimes commencing in February and sometimes lasting until the middle of May, the best flow of sap being when there is a diurnal alternation of thawing and slight freezing. See Maple.

The most popular modern method of tapping the trees is to bore a one-half inch hole not more than 1½ inches into the tree near the ground and to drive in a metal or wooden 'spile.' This conducts the sap and also serves to support the bucket, from which the sap is collected once or oftener each day and taken to a central plant to be boiled as soon after it arrives as possible, to avoid deterioration. All sorts of apparatus, including culinary utensils, are used for boiling the sap, but the most approved is a steam-heated evaporator, of which several makes are upon the market. In these the sap flows through a winding channel, emerging as the finished product, which, owing to its freedom from molasses, quickly solidifies if sufficiently evaporated.

On an average the sap contains about 3 per cent. of sugar, but occasionally exceeds 6 per cent., and at this average a yield of three pounds a year is considered profitable. Large trees and trees with rich sap often yield far more. The impurities of the sap as found in the sugar rarely exceed 5 per cent. There is, however, a small amount of insoluble material which is removed by skimming. Sometimes milk or white of egg is used as a clarifier, but usually no purifying agents are employed, reliance being placed on quick boiling and skimming to produce a light-colored and otherwise satisfactory sugar. The only impurity that causes trouble is the so-called 'sugar sand,' composed mainly of acid malate of lime, which collects on the bottom of the pans, interferes with the boiling, and makes the syrup cloudy and the sugar gritty.

Palm-Tree Sugar. The 'jaggery,' made principally in the East Indies from various species of palms (Phœnix, Borassus, Coccos, and other genera), is a dark-colored raw sugar made in a crude way by methods not essentially different from those described, except that a little lime is added as a clarifying agent. It plays a minor part in the world's markets.

Sugar Refining. Since all of the raw beet sugar and much of the raw cane sugar are unsuitable for table use, and since even the lighter grades of unrefined sugar are in small demand when compared to the snow-white granulated, loaf, and powdered sugars, the refining of raw sugars has become an important branch of the sugar industry. As usually conducted the process consists in dissolving the raw sugar in water, filtering through cloth to remove suspended matter, decolorizing by filtration through bone black (bone charcoal), and granulating in a vacuum pan as above described for sugar-cane sugar. For the manufacture of high-grade sugars with large, hard crystals, the process is sometimes modified, the raw sugar being washed with a dense syrup that removes the adhering molasses without perceptibly dissolving the crystals, which, when dissolved, form a syrup so light-colored as greatly to reduce or entirely obviate the necessity of filtering through bone black before the solution is placed in the strike pan for granulation.

Statistics of the Sugar Industry. The world's production of sugar in 1902-3, excepting that obtained from maple trees, is quoted below from the estimates given in Willett and Gray's *Weekly Statistical Sugar Trade Journal*, for September 17, 1903:

Sugar Crop of the World

Cane Sugar	Tons
Louisiana	300,000
Porto Rico	85,000
Hawaiian Islands	349,000
Cuba	975,000
West Indies (exports)	256,772
Mexico	115,000
Central America	23,500
British Guiana (exports)	105,000
Dutch Guiana	13,000
Venezuela	3,000
Peru	140,000
Argentina	130,000
Brazil	187,500
British India	15,000
Siam	7,000
Java	842,812
Philippine Islands (exports)	80,000
Queensland	76,626
New South Wales	21,000
Fiji Islands (exports)	35,500
Egypt	90,000
Mauritius	135,000
Réunion	35,000
Spain	28,000
Total cane-sugar production (Willett & Gray)	4,048,710
European beet-sugar production (Licht)	5,605,000
United States beet-sugar production (Willett & Gray)	195,463
Grand total cane and beet-sugar production	9,849,173

According to the reports of the Twelfth Census the maple sugar made on farms in the United States during the year 1899 amounted to 11,928,770 pounds, and the maple syrup to 2,056,611 gallons.

The annual per capita consumption of sugar in various countries is given in Willett, and Gray's *Weekly Statistical Sugar Trade Journal*, for March 14, 1901, as follows:

	Consumption per capita, 1899-1900
Germany	33.9 pounds
Austria	17.6 "
France	36.9 "
Russia	14.0 "
Holland	32.4 "
Belgium	23.3 "

	Consumption per capita, 1899-1900	
Denmark	54.8	pounds
Sweden and Norway	38.2	"
Italy	6.1	"
Rumania	7.8	"
Spain	10.6	"
Portugal	14.7	"
England	91.6	"
Bulgaria	7.7	"
Greece	7.2	"
Servia	6.2	"
Turkey	8.0	"
Switzerland	60.3	"
All Europe (Licht)	27.1	pounds
United States (W. and G.)	66.6	"

MOLASSES. Molasses is a viscid, usually dark-colored uncrystallizable liquid which seeps from the massecuite of sugar-cane or is thrown out by the centrifugal machine. The latter kind is reboiled as noted above; the former, however, being highly valued for its flavor and sweetness, is used as a food and for cooking. Since the introduction of the vacuum pan and the centrifugal machine it has become annually less plentiful in the market, the small quantities made being used in the regions where cane sugar is manufactured. Most of the so-called New Orleans molasses is composed of glucose flavored with some molasses from the sugar factories. Spurious maple syrup and sugar (see above) are made of cane sugar and glucose often flavored with an extract of hickory bark. No table molasses is made from the sugar beet, because the impurities cannot be removed by any known process. Processes have been patented for the manufacture of table syrup from beet roots, but they have hitherto been of little commercial importance.

Normally, cane molasses made by the open-kettle process contains about 30 per cent. cane sugar, 23 per cent. reducing sugar, and 47 per cent. water, ash, and impurities; that made in a large modern factory, 20 per cent. cane sugar, 25 per cent. reducing sugar, and 51 per cent. water, etc. Beet molasses contains 47 per cent. cane sugar, 5 per cent. reducing sugar, 20 per cent. water, 22 per cent. organic matter other than sugars, and 6 per cent. ash, etc. In sugar-manufacturing regions molasses is mixed with such bulky materials as cottonseed meal, cotton-seed hulls, etc., to be easily handled and fed to stock as a cheap source of carbohydrate food. In Europe several 'molasses feeds' have been proposed and one has been manufactured in commercial quantities from four parts bran, three parts beet-sugar molasses, and one part palm-nut cake. Another preparation composed of dried blood, peat, extracted beef pulp, and molasses has also been tried with favorable results.

MILK SUGAR OR LACTOSE. Sugar of milk, occurring only in the milk of mammals, is found to the extent of 4 or 5 per cent. in the milk of herbivorous animals. It is obtained by first curdling the milk with rennet or other agent to remove the casein and the fat, and then drawing off and evaporating the clear whey to a syrup in which, when cold and still, the milk sugar crystallizes and sinks. The deposit is recrystallized, after being dissolved in hot water, sometimes as hard cylindrical masses on strings. Sugar of milk is employed very largely for modifying cow's milk for the use of infants, in pharmacy, and as a food. See MILK; FOOD.

FOOD VALUE OF SUGAR. Since milk sugar and dextrose are used for human food to a far less extent than cane sugar, which they resemble somewhat closely in action, the statements in the following paragraphs are confined to cane sugar. In its food value sugar resembles starch, being considered a fat-former and a source of energy with a fuel value of 1860 calories a pound. Thus it is ranked as a more readily available heat-producer and force-conserver than starch (q.v.). From dietary statistics the conclusion is drawn that persons in well-to-do families in the United States consume about two pounds of sugar weekly, an amount that seems to be well utilized. The consumption of larger amounts is considered questionable economy both with respect to the purse and to the system. But excessive indulgence in food of any other sort is also wasteful and unwise. Thus the wholesomeness and utilization of sweetened foods is largely a matter of quantity or concentration, a simple dish flavored with sugar being considered easy to digest, but a heavily sweetened one eaten singly, more or less difficult because of its concentration. The bad effects popularly charged to sugar are misapplied.

Numerous bulletins on the sugar industry and sugar manufacture have been published by the Division of Chemistry, United States Department of Agriculture. Some of the more recent of these are as follows: *Sugar-cane Culture*—Bulletins 70 and 75; *Sugar from Sorghum*—Bulletins 26, 29, 34, 37, and 40; *Sugar Beet Culture*—Bulletins 27, 30, 33, 36, 39, 52, 64, and 74. A series of publications on the progress of the beet-sugar industry in the United States has also been published. Those for 1900, 1901, and 1902 are issued as Reports Nos. 69, 72, and 74 respectively.

See SUGARS.

SUGAR BEET (*Beta vulgaris*). A vegetable of the natural order Chenopodiaceæ, botanically the same species as the garden beet, important commercially as the source of a very large part of the world's supply of sugar. (See SUGAR, section on *Beet Sugar.*) The sugar beet flourishes upon a rich, deep, loamy soil in a climate having a temperature of about 70° during the growing season. The seed is planted and the crop cultivated and harvested by the finest machinery. The rotation of the crop with others is carefully planned and the proper fertilization of the fields has been a subject of much study by the experiment stations. Since the sugar content and yield are influenced by many factors, the sugar companies employ field experts to instruct the farmers how to grow beets in the proper way. Being a product of intensive cultivation, the sugar beet is especially suited to a thickly settled population. The average cost of growing an acre of sugar beets in the United States is about $30. The average yield in the best districts is about 12 tons, with an average sugar content of 14.5 per cent. This represents a yield of about 3900 pounds of sugar per acre, though higher yields have been reported up to 4800 pounds.

SUGAR-BEET INSECTS. The recent introduction and rapid spread of the sugar beet have resulted in the attacks of several insects not before known as injurious and have given a new food to others. A leaf-miner (*Pegomyia vicina*), 30 or 40 larvæ of which may be found in a single leaf, has produced serious damage in California. Many leaf-hoppers (q.v.) feed upon the leaves; also several plant and leaf bugs, and plant-lice, notably the common melon aphis (*Aphis gossipii*). Various cutworms (q.v.) are troublesome while the beets are young. Considerable damage has been done by the greenhouse leaf-roller (*Phlyctænia ferrugalis*). The so-called garden webworms, however, especially in the West, have done the greatest damage of all. Certain leaf-beetles injure the leaves, and the larvæ of some of them feed upon the roots. Much damage has been done by grasshoppers, non-migratory locusts, and blister beetles (q.v.), the imbricated snout beetle, and the army worm (q.v.). Toward the close of the last century the so-called beet army worm (*Laphygma flavimaculata*) defoliated thousands of acres of sugar beets in Colorado. The purslane caterpillar (*Copidryas Gloveri*), the purslane sphinx (*Deilephila lineata*), and several of the woolly-bear caterpillars also feed upon the leaves. Great damage has been done in the State of Washington by a root-louse known as the beet aphis (*Pemphigus betæ*), and a root mealy-bug has been found on the crown of the plant in Colorado. Several of the wireworms (q.v.) and white grubs (q.v.) also damage the roots.

Consult: Forbes, *Twenty-first Annual Report State Entomologist of Illinois* (Chicago, 1900); Forbes and Hart, *Bulletin No. 60 Illinois Agricultural Experiment Station* (Urbana, 1900).

SUGAR-CANE (*Saccharum officinarum*). A tropical and subtropical grass, originally a native of the East Indies. It was brought to Europe by the Crusaders, and in the fifteenth and sixteenth centuries found its way into the European colonies in the tropics. In China it extends to latitude 30° N., and in North America to 32°; in the Southern Hemisphere only to latitude 22° S. The plant is a perennial with a creeping root, sending up a number of many-jointed diversely colored stems, generally 8 to 12 feet high, 1 to 2 inches thick, and filled for about two-thirds of their length with a loose, sweet, juicy pith. The leaves are ribbon-shaped, 4 to 5 feet long, with a strong midrib. The flowers are in great diffuse pyramidal panicles a yard long.

Sugar-cane requires a deep rich soil and abundant moisture during the growing season. Low alluvial soils near the sea are preferable. The land is prepared with very large plows. The plants are propagated by cuttings. For this purpose the top joints are planted in rows 5 to 7 feet apart. Usually two continuous lines of canes are planted in the row. The largest varieties, in rich, moist soils, attain a height of twenty feet; but in dry, poor soils the height is sometimes scarcely more than six feet. The plant tillers like wheat, but not to the same degree. The cane ground is kept clean by shallow cultivation. The best varieties are ready for cutting in about eight or ten months from the time of planting, but other varieties require from twelve to twenty months. When the canes are fully ripe they are cut a little above the ground, stripped of their leaves,

SUGAR-CANE.

and tied in bundles. Fresh canes, called *rattoons*, spring from the root, so that the plantation does not require to be renewed for several years; but the canes of the first crop are the largest, and a gradual decrease of size takes place. The ordinary practice on sugar estates is to renew a part of the plantation every year. The sugar content of the cane ordinarily grown has for some time averaged about 10 per cent. Sugar-cane production is usually carried on by large plantations. It is a business of great risks, but large profits. It requires a large and sure source

of labor, especially at harvest. The yield of sugar varies greatly. In regions with a fertile soil, irrigation, and improved methods of culture about five tons of sugar per acre is produced. Yields of over ten tons per acre are authenticated. In Hawaii, where sugar-cane production has reached its highest perfection, yields of even fourteen tons of sugar per acre are known. This is obtained only by frequent plantings and scientific fertilization and irrigation of the crop. The leaves are sometimes used for feeding cattle. Efforts made by the Louisiana Experiment Station to make silage from sugar-cane refuse were unsuccessful, owing to the alcoholic and acetic fermentation induced by the residual sugar. The pressed residue from the mill, known as *bagasse*, is used for fuel. It is also employed as a fertilizer. See SUGAR, MANUFACTURE OF.

SUGAR-CANE INSECTS. The principal enemies of the sugar-cane in the United States are the sugar-cane beetle (*Ligyrus rugiceps*) and the sugar-cane borer (*Diatræa saccharalis*). The former belongs to the family Scarabæidæ, and breeds in the ground. The adult beetles make their appearance in early spring, bore into the stubble or into the young cane, and also work into the seed cane; the top leaves wither and the stalk is finally destroyed. The borer is the larva of a crambid moth which lays its eggs upon the leaves of the young cane near the axils, and the young borer, hatching in the course of a few days, penetrates the stalk at or near the joint and tunnels, usually upward, through the soft pith. It matures in thirty days or less, and there are several generations each year. It hibernates in the larval state in the lower part of the stalk or in the tap root. Burning the tops and volunteer cane, and laying down the seed cane in trenches beneath the surface of the ground, keep this insect in check.

In Hawaii there is a weevil borer (*Sphenophorus obscurus*) which does considerable damage. Stalks of the cane are frequently riddled with the galleries of the larvæ, and the galleries are filled with macerated fibre which the larva apparently pushes behind itself. When ready to pupate the tunnel is somewhat enlarged and a cocoon is formed of coarse fibre in which transformation takes place. In Australia there is a noctuid larva which bores downward from the tips of the plants. Certain scarabæid larvæ feed upon the roots, and the young plants are destroyed by wireworms. In the West Indies a bark-boring beetle (*Xyleborus piceus*) sometimes riddles the canes by its minute burrows, the larva working into the young sprouts from the stumps of previously cut canes. In Java there are three lepidopterous borers and a mealy bug which do some damage, and in Mauritius a somewhat troublesome scale insect known as *Icerya sacchari*. Consult various volumes of *Insect Life* (Washington, 1888 to 1895); Comstock, *Report on Insects Injurious to Sugar-Cane* (ib., 1881); Morgan, "Sugar-Cane Borer," in *Bulletin 9, Louisiana Agricultural Experiment Station* (Baton Rouge, 1891).

SUGAR-HOUSE, THE. A brick building on Liberty Street, New York, used by the British as a military prison during the Revolution.

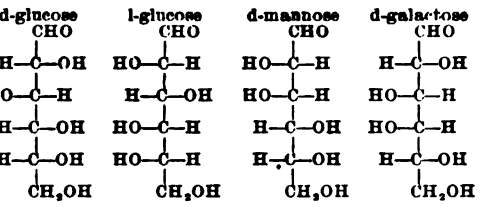
SUGAR OF LEAD. The common name for acetate of lead. See LEAD.

SUGARS (OF., Fr. *sucre*, from ML. *succarum*, *sacoharum*, from Gk. *σάκχαρ*, *sakchar*, *σάκχαρον*, *sakcharon*, sugar, from Ar. *sakkar*, from Pers. *shakar*, Hind. *shakkar*, from Prak. *sakkara*, sugar, from Skt. *śarkarā*, candied sugar, gravel, grit). A term applied to various substances composed of carbon, hydrogen, and oxygen (see CARBOHYDRATES), which are more or less sweet, are readily soluble in water, are colorless and odorless, and are usually crystallizable. They are widely distributed in nature as original products of vital processes in plants. They have an unparalleled importance in the organic world. In green plants they are formed from carbon dioxide and water by the chloroplasts (see PHOTOSYNTHESIS), and are transferred by diffusion to all parts of the plant body to be used directly in the metabolism of the plant for the manufacture of proteid substances, or to be stored for future use, sometimes as glucose (e.g. in the onion bulb), sometimes as saccharose (e.g. in the beet), and sometimes as other widely different substances into which they have been converted. (See STORAGE.) If formed more rapidly than they can diffuse away, sugars may be condensed into starch in the chloroplasts themselves. At times of renewed growth, as in the germination of seeds and the sprouting of tubers and bulbs, the plant draws upon these stores of carbohydrate. If the storage has been in the form of cellulose, starch, inulin, or cane sugar, the stored food must be converted by means of enzymes into a hexose sugar before it can be utilized. The stored sugars of plant tissues form one of the most valuable sources of animal food.

Sugars found in the bodies of animals or in the excreta therefrom are believed to be derived from substances of vegetable origin. The sugars have been variously classified according to their chemical and physical properties as fermentable and non-fermentable; reducing and non-reducing; and dextro-rotary, lævo-rotary, and inactive, according to their effect on polarized light.

FERMENTABLE AND UNFERMENTABLE SUGARS. These include the sugars that undergo change or decomposition under the influence of microörganisms; glucose, for example, and certain other sugars are thus changed into alcohol (q.v.) by the action of yeast. This term and method of classification have become unsatisfactory because of greatly increased knowledge of the action of the lower forms of life and enzymes on sugars and other substances. (See FERMENTATION; ENZYME.) Many sugars, however, that are not acted upon by one organism are readily decomposed by another, and so the subdivision of sugars into fermentable and unfermentable is of at least doubtful value. For example, milk sugar does not yield alcohol with yeast without first being hydrolyzed, but undergoes the lactic acid fermentation immediately.

REDUCING SUGARS. Certain sugars possess the property of reducing compounds of copper, silver, and other easily reducible metals in alkaline solution, the reduction being generally more rapid at the boiling point of the liquid. In some cases the compounds are reduced to lower oxides, which are precipitated, as in the case of copper; in other cases the reduction is complete, the free metal being precipitated. An alkaline solution of copper (see FEHLING'S SOLUTION) is the one usually employed for testing the reducing power of sugars. The amount of reduction depends



upon the amount of a given sugar present; the process is therefore used for the quantitative determination of reducing sugars. Among the important reducing sugars are d-glucose (dextrose or grape sugar), d-fructose (lævulose or fruit sugar), maltose, lactose (milk sugar), and 'invert sugar' (see below). Sucrose (cane sugar), raffinose, melicitose, and stachyose are the principal non-reducing sugars known.

OPTICALLY ACTIVE SUGARS. The property possessed by sugars of rotating the plane of polarized light to the right or left when passed through their solutions has long served as a basis for classification. Sugars possessing this property are said to be optically active, and those which do not are said to be inactive. Those that turn the plane of polarization to the right are called dextro-rotatory; those to the left, lævo-rotatory. The amount of rotation is proportional to the amount of the sugar in a given volume of the solution, and this is taken advantage of for the quantitative determination of sugars. A special form of the polariscope (q.v.), called a saccharimeter, is in common use for this purpose. For the polarimetric determination of sucrose (cane sugar), a weighed quantity of the sugar, syrup, or other material is dissolved in water; the solution is treated with lead acetate or other clarifying agent, diluted to 100 cubic centimeters, filtered, and placed in the observation tube of the polariscope. The observer then ascertains the percentage of sugar contained in the material under investigation by simply looking into the instrument, adjusting it to compensate for the change in the field of vision caused by the presence of the sugar solution, and by reading the percentage of sucrose directly from the scale of the instrument.

Since 1880 the sugars have formed the subject of numerous brilliant researches, notably those of H. Kiliani and Emil Fischer. In the early eighties Kiliani demonstrated that d-glucose (dextrose or grape sugar) and d-fructose (lævulose or fruit sugar) are aldehyde and ketone derivatives, respectively, of hexahydric alcohols, the former containing one aldehyde group and the latter one ketone group. (See ALCOHOLS; ALDEHYDES; KETONES.) He also showed that arabinose is an aldehyde of the pentahydric alcohol, arabite, and has the formula $C_5H_{10}O_5$. The molecules of all carbohydrates had been believed to contain six carbon atoms or some multiple thereof. But sugars containing three, four, five, six, seven, eight, and nine atoms of carbon in their molecules are now known; these are designated respectively by the class names trioses, tetroses, pentoses, hexoses, heptoses, octoses, and nonoses. According as the individual members of each of these classes contain aldehyde or ketone groups (see ALDEHYDES; KETONES), they are designated as aldoses or ketoses; for example, aldohexoses and ketohexoses. These classes together constitute the group of carbohydrates known as monosaccharides. Their molecules contain as many atoms of oxygen as atoms of carbon, except in the case of certain of their synthetic derivatives.

There are other groups of sugars, in the molecules of which there are fewer atoms of oxygen than of carbon. When the latter are treated with acids or enzymes they are hydrolyzed, i.e. each one of their molecules combines with one or more molecules of water and simultaneously splits up into two or more monosaccharide molecules. These more complex sugars are called disaccharides when each of their molecules yields two monosaccharide molecules; trisaccharides when one molecule yields three monosaccharide molecules; and polysaccharides when one molecule yields several monosaccharide molecules on hydrolysis; for examples, see descriptions of individual sugars below.

In the course of his work, Emil Fischer prepared a number of hitherto unknown sugars by purely synthetic processes. He showed that the monosaccharides furnish excellent examples of the necessity for the chemist to consider the space relations of the atoms in the molecule. (See STEREO-CHEMISTRY.) According to the theory of Le Bel and Van 't Hoff sixteen isomeric aldohexoses are possible, since their molecules contain each four asymmetric carbon atoms. Three of these occur in nature or are obtainable from natural carbohydrates by hydrolysis. Eight others have been produced in the laboratory. The aldopentose and ketohexose molecules each contain three asymmetric carbon atoms, therefore but eight stereo-isomers are possible in each case. No ketopentoses are known with certainty. Two aldopentoses are readily obtainable from natural sources; three or more others have been prepared in the laboratory. Only two natural ketohexoses are known; one or more others have been prepared in the laboratory. The character of the differences between the hexoses is illustrated by the following stereo-chemical formulæ:

Formic aldehyde and glycerin, both of which have been produced synthetically, are the substances from which certain sugars have been synthesized by Fischer and others. Formic aldehyde, CH_2O or H-COH, may be regarded as the simplest of the monosaccharides and be designated as monose. Bayer (1870) suggested that this substance is the first product of the reduction of carbon dioxide in the green parts of plants, and that starch and other carbohydrates are formed by its polymerization. Its formation in plants has never been satisfactorily demonstrated, but it is known readily to undergo polymerization or condensation to form paraform $(CH_2O)_n$ and trioxymethylene $(CH_2O)_3$. In 1861 Butleroff obtained by condensation of trioxymethylene a sweet, sugar-like body which he called 'methylenitan.' Loew (1885) obtained in a similar manner 'formose' from oxymethylene, and later 'methose.' The last named is more sugar-like than 'formose' in that it is fermented with yeast. Fischer regards these substances as mixtures of different hexoses, including among others d-acrose, which he also obtained from glycerose, which is a mixture of glyceraldehyde and dioxyacetone, obtained by the careful oxidation of glycerol (glycerin). From d-acrose [(d + l) fructose] Fischer prepared d-fructose, d-glucose, d-mannose, and the l- modifications, or optical antimeres, of each of these bodies.

The synthesis of each one of these bodies was accomplished by a series of complicated reactions which are fully described in text-books on chemistry. Fischer's work was greatly facilitated by the use of phenylhydrazine, which forms readily crystallizable compounds with the hexoses, called osazones. These compounds are insoluble in water and eminently suited for the separation and identification of the different sugars. By means of the cyanhydrine reaction he changed hexose sugars into heptoses, and these in turn into octoses and nonoses. The combination of monosaccharides to form disaccharides has only recently been accomplished by Fischer. Among a number of his synthetic disaccharides is one which he designates galactosidoglucose (because it is made by the union of one molecule of d-galactose with one molecule of d-glucose), and which closely resembles the natural sugar melibiose. In an article published in September, 1902, he says that if further investigations confirm his conclusion that the two sugars are identical, "melibiose is the first natural disaccharide to be produced synthetically."

The more important sugars are mentioned in the following table with brief descriptions of those of commercial importance:

I. MONOSACCHARIDES

1.	Monose, CH_2O.	Formic aldehyde.
2.	Biose, $C_2H_4O_2$.	Glycollic aldehyde.
3.	Triose, $C_3H_6O_3$.	Glycerose, obtained by oxidation of glycerin.
4.	Tetrose, $C_4H_8O_4$.	Erythrose, obtained by oxidation of erythrin, a tetrahydric alcohol found in lichens and algæ.
5.	Pentoses, $C_5H_{10}O_5$.	
	A. Aldopentoses.	l-arabinose (arabinose, arabose, pectinose, pectin-sugar) and xylose (wood-sugar), obtained alone or mixed with other sugars by hydrolysis of gums and other vegetable substances.
		d-arabinose, l-xylose, and ribose, obtained synthetically.
	B. Ketopentoses.	None known with certainty.
	C. Methyl pentoses, $CH_3C_5H_9O_5$.	Fucose, from seaweed; rhamnose, widely distributed in the vegetable kingdom in the form of glucosides: chinovose, obtained by the decomposition of chinovite, a constituent of cinchona bark.
6.	Hexoses. $C_6H_{12}O_6$.	
	A. Aldohexoses.	d-glucose (dextrose, grape sugar or starch sugar), see GLUCOSE; d-mannose (mannose, isomannose or seminose), obtained by the oxidation of mannite and by the hydrolysis of various vegetable materials; d-galactose (see below).
		l-glucose, l-mannose, l-galactose, d-gulose, l-gulose, d-idose, l-idose, d-talose, and l-talose, obtained synthetically.
	B. Ketohexoses.	d-fructose (levulose or fruit sugar; see below); scrbinose, from mountain ash berries.
		l-fructose, obtained synthetically.
	C. Hexoses of natural origin and of unknown nature.	Chondroglucose, crocose, eucalyn, hederose, indiglucin, locaose, paraglucose, phlorose, scammonose, skimminose, solanose, tewfikose (forms 5 to 6% of the milk of the Egyptian buffalo), and wine sugar.
	D. Methyl hexoses, $CH_3C_6H_{11}O_6$.	a-rhamno-hexose and β-rhamno-hexose, obtained synthetically.
7.	Heptoses, $C_7H_{14}O_7$.	Six heptoses and a methyl derivative have been prepared synthetically.
8.	Octoses, $C_8H_{16}O_8$.	Four octoses and a methyl derivative have been prepared in the laboratory.
9.	Nonoses, $C_9H_{18}O_9$.	Two have been produced artificially.

II. DISACCHARIDES

1.	Derivatives of pentoses, $C_{10}H_{18}O_9$.	Di-arabinose or arabinon, obtained from arabinic acid (metapectic acid).
2.	Derivatives of hexoses, $C_{12}H_{22}O_{11}$.	Sucrose (cane sugar, saccharose, saccharon, or saccharobiose), lactose (milk sugar, lactobiose, or lacton), and maltose (maltobiose, malt sugar, amylon, diglucon, ptyalose, or cerealose); see below).
		Trehalose (mycose, trehabiose) from ergot and other fungi; isomaltose from malted grain; melibiose, formed together with d-fructose by careful hydrolysis of raffinose; turanose, formed together with d-glucose by hydrolysis of melecitose; cyclamose, from cyclamen tubers; agavose, from the juice of the agava; and several produced synthetically by Fischer.

III. TRISACCHARIDES

All are derivatives of the hexoses, $C_{18}H_{32}O_{16}$.		Raffinose (melitriose, melitose, gossypose, or cotton sugar; see below); melecitose (melecitriose), from the manna of *Pinus larix*; stachyose, from the tubers of *Stachys tuberifera*; gentianose, from the roots of *Gentiana lutea*; lactosinose (lactosin), from the roots of certain plants of the order Caryophyllaceæ; and secalose, from unripe rye.

SUCROSE, CANE SUGAR, OR SACCHAROSE. This is commercially the most important sugar. It and the products of its hydrolysis, 'invert sugar,' and the sugars that compose 'invert sugar' (d-glucose and d-fructose) are the most important sugars, considered from the point of their wide distribution in fruits and vegetables used for food by man and the lower animals. (For the commercial sources of cane sugar, see SUGAR, MANUFACTURE OF.) White granulated sugar, whether made from sugar-cane or beet roots, contains between 99 and 100 per cent. of pure sucrose or cane sugar. In many plants it is found associated with 'invert sugar,' which seems to be changed to cane sugar during the process of ripening. When cane sugar is hydrolyzed by the action of acids or enzymes, each molecule yields one molecule of d-glucose and one molecule of d-fructose, a mixture called 'invert sugar,' as explained above.

Cane sugar is readily crystallized in the form of monoclinic hemihedral tables which contain no water of crystallization. These crystals are well exemplified in loaf sugar, rock candy, and granulated sugar, the coarseness of which depends upon the size of the crystals. It dissolves in about one-half of its weight of water and is much more soluble in hot water; it is dissolved with difficulty in strong alcohol. Its specific gravity is 1.606. It melts at 160° C. (320° F.), and with care may be cooled to a colorless glass-like mass; if the temperature is somewhat higher the solidified mass is colored and constitutes the so-called 'barley sugar.' At 200° C. (392° F.) decomposition and marked coloration begin, caramel is formed, and as the heat is continued gases are evolved and finally only a black char remains. Sucrose unites with the oxides of calcium and other metals to form saccharates, which are of importance as a means of separating sugar from beet-root molasses. While cane and other sugars in dilute solutions are very prone to undergo fermentation and change, they possess considerable antiseptic power in concentrated solution, which is utilized in dried fruits, preserves, etc.

LEVULOSE, d-FRUCTOSE, OR FRUIT SUGAR. This occurs in almost all sweet fruits with d-glucose.

It is crystallized with difficulty, and melts at 95° C. (203° F.). It is readily obtained by hydrolysis of inulin, a polysaccharide which occurs in many plants. It is less soluble than d-glucose, and is as sweet as cane sugar. Levulose is used as a substitute for sugar in the food of diabetic patients. Some of the commercial forms of levulose for this purpose are called 'diabetine.'

RAFFINOSE, MELITRIOSE, MELITOSE, OR COTTON SUGAR. This occurs in rather large quantity in Australian manna (from varieties of Eucalyptus), in cottonseed meal, and in small quantities in sugar beets, the manufactured sugar from which sometimes contains small amounts, but the molasses much the greater proportion. It forms characteristic crystals and is strongly dextro-rotatory. When hydrolyzed by acids each molecule yields one molecule of d-glucose, one of d-fructose, and one of d-galactose.

MALTOSE, MALTOBIOSE, MALT SUGAR, OR AMYLON. This is formed, together with dextrin and dextrose, when starch is hydrolyzed with enzymes or acids. It is present in malted grain, in commercial glucose, and in the mash of beer and whisky. It is usually obtained in the form of crystalline crusts. When hydrolyzed it is converted into d-glucose.

MILK SUGAR, OR LACTOSE. This occurs in the milk of mammals. It crystallizes in white hard rhombic prisms, with one molecule of water of crystallization, which is dissipated at 140° C. (284° F.); at 205° C. (400° F.) it melts with decomposition. It dissolves in six parts of water at the ordinary temperature and in 2½ parts of hot water; is insoluble in alcohol, and has a faint, sweet taste. When hydrolyzed by the action of acids it is converted into equal parts of d-glucose and d-galactose. See SUGAR, MANUFACTURE OF.

GALACTOSE. This is of interest as one of the inversion or hydrolysis products of raffinose and milk sugar. It is also obtained by the hydrolysis of a number of polysaccharides occurring in vegetable substances and called 'galactans.'

SUG'DEN, EDWARD BURTENSHAW. A celebrated English jurist and author. See SAINT LEONARDS, EDWARD BURTENSHAW SUGDEN, BARON.

SUGER, sụ'zhâ', ABBÉ DE SAINT DENIS (1081-1151). A French churchman, statesman, and historian. He spent a large part of his youth in the Abbey of Saint Denis, and was for a time a student with Prince Louis, afterwards Louis the Fat, with whom he always remained on terms of close friendship. In 1122 he became abbé of Saint Denis, and he carried out many reforms and greatly increased the prosperity of his charge. He was frequently engaged in affairs of State, and when Louis VII. went on the Second Crusade Suger acted as Regent in his absence and administered the affairs of the kingdom with great ability. Shortly afterwards, although he had opposed the previous one, Suger preached another crusade, but died in 1151 before it could be carried out. He wrote in Latin a *Life of Louis VI.* (c.1140), which is one of the chief sources upon the history of the period. His complete works were published at Paris in 1867. Consult Meanult, *Suger* (Paris, 1884), and Cartellieri, *Abt Suger von Saint-Denis* (Berlin, 1898).

SUGGESTION (Lat. *suggestio*, intimation, suggestion, from *suggerere*, to suggest, supply, from *sub*, under + *gerere*, to carry). A term used in four different senses in psychology. (1) In its broadest significance suggestion is a hint, a prompting, the insinuation of an idea into consciousness. An orator may suggest, e.g. impatience to his audience by a shrug of his shoulders. (2) Suggestion is used more narrowly as a synonym for association (q.v.). The idea of Spain suggests (or 'associates with') war, war suggests Cuba, Cuba suggests sugar, etc. (3) Still more specifically, suggestion implies a peculiar mode of creating belief. One may, e.g. create by suggestion the belief that a piece of metal is hot by handling it as if it were burning one. (4) Finally, suggestion indicates a means of directing the consciousness and the movements of a hypnotized subject. The operator is said to 'suggest' to his subject that he see an object which is not in reality present, or that he react to an imaginary situation. The first two definitions contemplate suggestion simply as an incentive to 'reproduction' (see REPRODUCTION OF IDEAS); the last two as a determinant of belief, under usual or 'normal' and under unusual or 'abnormal' conditions. Between the third and the fourth uses of the word no strict line of demarcation can be drawn. (See HYPNOTISM.) The term is most accurately employed in one of these narrower senses, as an influence upon belief. Belief (q.v.) may appear either as a mood of acquiescence (one believes, e.g. when one is told that $2 + 3 = 5$), or as a conviction following upon deliberation (one believes the conclusion reached by a series of 'sound' arguments). Just how suggestion may occasion belief under unusual circumstances, as in hypnosis, psychologists are not entirely agreed, but two theories have been worked out in detail. (1) The first (Wundt's) maintains that in hypnotic suggestion there is a 'constriction' of consciousness. Few ideas enter at once; only those that are aroused directly by association. 'Foreign' ideas are barred out. The narrowing of the field of consciousness implies, according to the theory, an increased clearness and intensity in the ideas attended to. This fact is explained physiologically by hyperæsthesia of a limited cortical area and a corresponding anæsthesia in the other areas. The result is that whatever comes to mind is peculiarly vivid and forcible and stands free from contradicting ideas. This is synonymous with belief. (2) The other theory (Lipps's) sees the essence of suggestion in an unusual inhibition of experience which, if it could come before the mind, would destroy belief (e.g. a hypnotized person believes the operator's statement that he is a king or a cat, because his past experience is in abeyance: it is beyond his control: he is unable to criticise or to oppose any statement made). The theory rejects physiological explanations and substitutes 'unconscious ideas.' Both theories agree that lack of conflicting ideas is essential. There is no room in hypnotic suggestion for deliberation and choice. To this we must add a feeling element, in the mood of acquiescence.

SUHL, zōōl. A town of the Prussian Province of Saxony, Germany, on the Lauter, 12½ miles north by east of Meiningen (Map: Prussia, D 3). Important for its manufactures of firearms since the fifteenth century, Suhl has been called the 'armory of Germany.' Population, in 1900, 12,617.

affords ground for forfeiture of a policy of life insurance.

The statistics of suicide are by no means satisfactory, as motives always exist for the concealment of the cause of death, and published figures are likely to be too low. This trouble is partly overcome when figures are used comparatively, as in the following table, showing the average annual number of suicides per million of population in various countries during the nineteenth century:

	1831-35	1841-45	1851-55	1861-65	1871-75	1887-91	Recent
England and Wales	62.8*	64	64	66	66	81	90
Ireland	10	.....	.....	.....	18	24	.....
Prussia	96	110	130	122	134	197	193
Saxony	158†	198	248	264	299	322	306
France	64	85	100	124	150	218	236
Belgium	39	62	.....	55‡	68	120	116
Italy	.....	.....	.....	28	35	52	.....

Sweden	69	66	71	76	81	119	.....
Norway	97	107	107	85	73	66	.....

* 1831-1840. † 1836-40. ‡ 1856-65.

SUICIDE (from Lat. *sui*, of one's self + *-cidium*, a killing, from *cædere*, to kill). The intentional taking of one's own life. Among uncivilized peoples suicide is by no means unknown, though it has generally been regarded as uncommon. It is favored by the teaching of some Oriental religions, but expressly forbidden by the Koran. Aristotle condemned suicide as unmanly, and early Greek custom accorded dishonorable burial to the perpetrator; but later practice, especially under influence of the Stoics, was much less severe. The Romans, also affected by Stoic doctrine, recognized many legitimate reasons for suicide and punished with confiscation of property only suicides committed to escape punishment for a grave crime. The Justinian code admitted seven excuses for suicide, ranging from madness to mere life-weariness. Under Christianity the spirit of law and custom was radically modified. To Saint Augustine suicide was essentially a sin, and several Church councils, from the fifth century, deprived the corpse of the ordinary rites of the Church. Mediæval law usually provided confiscation of the suicide's property, while custom decreed indignities to the corpse, such as dragging by the heels face downward, as in France, or burying at the cross-roads with a stake through the body, as in England. Later English law compelled forfeiture of lands and goods in all cases of suicide, but the requirement came to be frequently evaded through the granting of a coroner's verdict of insanity, and the law itself was abolished in 1870. A statute of 1823 made it legal to bury suicides in consecrated ground, but it was not till 1882 that religious services were expressly permitted. In France at the present time neither suicide nor attempt at suicide is punishable. In the United States suicide is not a crime, but it is unlawful, and an unintentional killing of another during an attempt at self-destruction is homicide. An attempt at suicide is a common-law misdemeanor, and in some States a felony by statute. Thus in New York, aiding a suicide is manslaughter in the first degree, aiding an attempt at suicide is felony, and the attempt itself by a sane person is felony, punishable by not over two years in State prison, or a fine of not over $1000, or by both. Suicide generally

The remarkable differences which appear between countries are due rather to race and national characteristics than to climate. This is well shown by suicide rates in the United States. In 1900 in the registration area persons with mothers born in France had a suicide rate (per million) of 220; Germany, 193; England and Wales, 104; Ireland, 61; Russia and Poland, 58; Italy, 51. In the registration area as a whole the rate was 103 in 1890 and 118 in 1900, being very much higher for white persons than for colored. The most notable difference of rate is that occasioned by sex, males usually constituting from four-fifths to three-quarters of the total suicides. Statistics of several States and of foreign countries indicate that the preponderance of males has been increasing during recent decades. When age is considered together with sex, it appears that while suicide in general increases with age, the ages at which women most tend to self-destruction are much under the corresponding ones for men. Thus in the United States (1900) there were out of 1000 suicides at known ages, 1.2 committed by males under 15 years, but 7.8 by females; for the age period 15 to 19 the rate was 18.8 for men, 100.5 for women; for 30 to 34 years it was 103.4 and 109.7 respectively; while for 40 to 44 the male rate was in excess, 117.3 to 90.1; and the men then continue to preponderate up to 85 years. Married people show a lower suicide rate than single, and single than widowed or divorced persons. Large cities have an unfavorable influence. The rate in Dresden is more than 500 per 1,000,000; in Paris, more than 400; in London, about 230; in Berlin, 260; in Saint Petersburg and Rome, less than 100. In 1890 the rate in Massachusetts was 84, but in Boston it was more than 120; in New York State (1890) it was 95, but 97 in Brooklyn and 150 in Manhattan (New York City).

Suicides among the young are especially prevalent in the great centres. The professional and commercial classes are more prone to suicide than are others; artisans evince higher rates than do laborers; while among soldiers and criminals the rates are extremely high. The rates for summer or late spring are always much above those for the other seasons, the maximum

usually occurring between April and July, the minimum in January or December. The early part of each month and the early days of the week show a relative preponderance. Other interesting correlations appear in the methods by which suicide is accomplished. In the aggregate the order of preference in method is: Hanging, drowning, shooting, cutting or stabbing, falling from a height, and asphyxiation or poison. In cold countries drowning is naturally less favored than in the south; the use of firearms is specially prominent in Italy; of cutting or stabbing in Prussia; of poison in England. As would be expected, female suicides employ firearms less than male. In England drowning is the recorded means for more than a quarter of the women committing suicide, and poison for about a seventh; but only 15 per cent. of male suicides drown themselves, and only a twelfth use poison.

The study of the motives to suicide can be more successfully pursued by psychologists and physicians than by the statistician. Definite mental disorders usually appear as the direct cause of a third of all suicides, but a very much larger proportion of cases show evidence of mental or physical abnormality. Suicidal tendency, like insanity, has been observed to be inherited. Alcoholism is a frequent cause. Emphasis upon biological influences has led some writers to regard suicide as always being, like certain diseases, a specific tendency of the individual. But the social causes of suicide are not to be underestimated. Imitation and the desire for notoriety undoubtedly affect suicides, and though perhaps too much stress has been laid upon the influence and the hurry and strain of modern business, there can be no doubt that many contemporary conditions which stimulate suicide, especially in great cities, are, like the predisposing causes of alcoholism, largely under social control.

SUIDÆ. The swine family. See SWINE.

SU'IDAS (Lat., from Gk. Σουΐδας, *Souidas*). The author of a great Greek lexicon, which was compiled probably in the middle of the tenth century. The work which is current under his name is a compilation giving the result of grammatical, lexicographical, historical, and literary studies. It is especially valuable for its articles touching the latter field, and the information which they contain is indispensable for our knowledge of the writers of antiquity. It is clear that the lexicographical portions were drawn from the lexica of Harpocration and Helladius, and certain other lexica and grammatical works which cannot be absolutely determined. He further employed excellent scholia to Aristophanes, scholia to Sophocles similar to those now found in the codex Laurentianus, Homeric scholia similar to those found in the codex Venetus B, and the older scholia to Thucydides. In his historical and theological articles it is more difficult to determine his sources, but his chief authority seems to have been the work of Constantinus Porphyrogenitus and the chronicle of Georgius Monachos. His literary articles were probably drawn in large measure from the *Onomatologos* of Hesychius Milesius, which he possessed in an abridged form. He employed also the notices of the comic poets preserved in Athenæus; but he added much from his independent reading. The work is best edited by Bernhardy (1834-53). The edition by Bekker (1854) is far inferior.

SUI JURIS, sōō'ī jōō'rĭs (Lat., of his own right). A Latin phrase employed to describe a person competent to perform legal acts. (See CIVIL LAW; PATRIA POTESTAS.) The meaning of the phrase has been extended in modern times to denote a person who is capable of taking care of himself.

SUIR, shōōr. A river of Ireland. Rising in County Tipperary, it forms, in part, the boundary between that county and County Waterford and then the boundary between Waterford and County Kilkenny. It unites with the Barrow to form Waterford Harbor, after a course of about 100 miles. For boats of about 55 tons it is navigable to Clonmel in Tipperary.

SUITE (Fr., succession, following), or PARTITA. In music, one of the oldest of cyclical forms. It had its origin in the sixteenth century, when the Stadtpfeifer began to perform several national dances in succession, which were of contrasting tempi, but all in the same key. During the seventeenth century German composers for the pianoforte applied the name partita to their *doubles* (a series of variations). (See VARIATION.) The form reached its culmination in the suites of J. S. Bach. The style of the suite is not so much contrapuntal as 'elegant.' The four obligatory movements are: (1) allemande, (2) courante, (3) sarabande, (4) gigue. As a rule, however, there were more movements, which were inserted after the sarabande. Such additional movements were known as *intermezzo* (q.v.). In modern times composers have also written suites for orchestra, which, however, but slightly resemble their prototypes. Some of the movements are not dance forms, and the principle of contrasting keys is also introduced. See DANCING; SONATA; SYMPHONY.

SUITS AT LAW AND EQUITY. See ACTION; EQUITY.

ŚUKASAPTATI, shōō'kă-săp'tă-tē (Skt., seventy [stories] of a parrot). A collection of Sanskrit prose stories. These tales, seventy in number, are told by a parrot to the wife of a merchant who is away on his travels. She is inclined to be unfaithful to her husband, and consults the parrot regarding her plans. The bird cleverly pretends to approve of her intentions, but points out to her the dangers of detection, and induces her to promise not to meet any lover unless she can extricate herself as such and such a person did. This rouses her

curiosity, and the parrot tells the story as far as the dilemma, which he asks her to solve. Unable to do this, she promises to remain at home that night on condition that the parrot will tell her the answer the following evening. In this way she is kept faithful until her husband returns. The story is very popular in India and has been translated into Persian as the *Tūṭīnāmah*. The Śukasaptati exists in two recensions. The shorter one was edited (Leipzig, 1893) and translated (Kiel, 1894) by Schmidt, who also edited (Munich, 1898) and translated (Stuttgart, 1899) the longer version. Consult Schmidt, *Ueber die Śukasaptati* (Halle, 1898).

SUKHĀVATĪ, sōōk-hä'vȧ-tē' (Skt., blissful). The 'Land of Bliss' into which those Buddhists are reborn who put their trust for salvation in Amitabha Buddha, the Buddha of boundless light, life, and mercy, invented by the founders of the Northern or Mahayana (q.v.) School. It is situated in some far distant world in the western quarter of the universe, separated from this world by tens of millions of Buddha worlds, and is presided over by Amitabha. Here there is no difference between gods and men, and sexual distinctions are unknown. There is no more toil, no hunger, nor pain of any kind, no thirst, and neither summer nor winter, no day, no night; no heat to scorch, no cold to chill; no sin, no suffering, no distress of any kind; no torments, and no prisons for punishment. To attain to rebirth in this paradise the performance of good works in this life is not necessary. Simple trust in the mercy of Amitabha is sufficient. It may even be attained by repeating the name of Amitabha two, three, four, five, six, or more nights before death. Among the common people this doctrine of a pure land of practically unending bliss has superseded the doctrine of Nirvana (q.v.).

SULEIMAN, sōō'lā-mān. A Turkish sultan. See SOLYMAN II.

SULEIMANIEH, sụ-lā'mȧ-nē'ye. A town of the Vilayet of Mosul, Turkey in Asia, 93 miles south of Bagdad, east of the Euphrates River. It commands several trade routes to Persia. Population, about 15,000.

SULEIMAN PASHA, sōō'lā-mān' pȧ-shä' (c.1840-92). A Turkish general, born at Constantinople. He was trained at the military school in Constantinople, entered the army, and attained the rank of major in 1867, when he served in Crete. In 1873 he was a colonel and instructor in the military school, of which he later became sub-director, with the rank of general of brigade, in 1874. He took part in the deposition of Abdul Aziz, May 30, 1876, and was made general of division by Amurath V. In 1877 he was made marshal. In the early part of the Russo-Turkish War (q.v.) he fought against General Gurko, whom he defeated at Eski-Zaghra (July 31-August 1, 1877) and forced to retreat into the Balkans, failing, however, in his desperate attempts to make himself master of the Shipka Pass. From October to December he commanded the Turkish Army of the Danube and was then intrusted with the command of the Turkish forces south of the Balkans. At Philippopolis, January 15-17, 1878, he was decisively defeated. This misfortune led to a heavy sentence of imprisonment, but he was afterwards pardoned.

SULFONAL. See SULPHONAL.

SULIMAN (sōō'lē-mān') **MOUNTAINS.** A range of mountains in the northeastern part of Baluchistan, near the borders of the Punjab, India (Map: India, A 2). It forms part of the eastern boundary of the great Iranian Plateau, toward which it sends numerous spurs, while on the east it falls steeply into the Indus Valley. Its highest point, the Kaisargarh, has an altitude of 11,320 feet.

SULINA, sōō-lē'nȧ. The central arm of the delta of the Danube (Map: Balkan Peninsula, G 2). Though not the largest in volume, it is the principal channel for navigation and has been made navigable for the largest vessels by means of large jetties and other engineering works conducted since 1858 by the International Danube Commission. At the mouth of the channel lies the little town of Sulina, whose harbor is a free port from which 11,411 vessels, aggregating 1,830,000 tons, cleared in 1901.

SULIOTES, sōō'lē-ōts. A tribe of Turkish subjects of mixed Greek and Albanian blood, who derived their name from the Suli Mountains, near Parga, in Epirus, to which they fled from the Turks in the seventeenth century. Their persistent opposition to Turkish rule brought them into constant trouble and won for them a reputation for bravery and patriotism. Overcome in 1803 by Ali Pasha of Janina, they left their mountains and fled to the islands off their native shore. In 1820 Ali Pasha invoked their aid in his fight for the independence of Albania. The forces of the Sultan were victorious and drove some of the Suliotes to their old mountain retreats, but more to the island of Cephalonia. Later they are found warring on the side of Greek independence, their most celebrated leader being Marco Bozzaris (q.v.). Many of them have migrated into Greece. Consult: Perrhaebos, *History of Suli and Parga* (London, 1823); Lüdemann, *Der Suliotenkrieg* (Leipzig, 1825).

SULLA (*Hedysarum coronarium*). A perennial leguminous fodder plant, native of Southern Italy and similar Mediterranean regions, where it has been in cultivation since about 1766. It is a leafy plant four to six feet tall, bearing numerous clusters of showy flowers. In the United States the seed is usually sown with fall wheat or oats in well-prepared soil, and after the removal of the cereal crop in the spring the sulla develops rapidly and by June is ready to cut. Sulla ranks with alfalfa as a forage crop, but does not seem as well adapted to the South as alfalfa. It is said to be preferred to alfalfa in more tropical regions, since it is better adapted to tropical conditions, but because it is susceptible to frost it is adapted to few regions of the United States.

SUL'LA, LUCIUS CORNELIUS (surnamed FELIX) (B.C. 138-78). A celebrated Roman general and statesman, born at Rome of a family belonging to the clan Cornelia. In B.C. 107 he was elected quæstor, and sent to Africa with cavalry that the consul Marius (q.v.) required for prosecuting the Jugurthine war. He rapidly acquired a series of important services by inducing Bocchus, the Mauretanian King, to surrender Ju-

gurtha (B.C. 106). In the campaigns that followed (B.C. 104-101) against the Cimbri and Teutones, Sulla's reputation continued to rise. For several years after the destruction of the barbarians Sulla lived quietly, taking no part in public affairs; but in B.C. 93 he stood for the prætorship, and won it by a liberal distribution of money among the people. Next year he was sent to Cilicia as proprætor, to replace Ariobarzanes on the throne of Cappadocia, from which he had been driven by Mithridates. In the Social War (q.v.) the successes of Sulla threw those of Marius into the shade, and the mortification of the latter was deep and bitter. In B.C. 88 Sulla was elected consul along with Q. Pompeius Rufus, and the senate conferred on him the command of the Mithridatic War. At this Marius, who desired the command for himself, precipitated a civil war. Allying himself with the tribune P. Sulpicius Rufus, a political adventurer in difficulties, Marius placed himself at the head of the new Italian party, on whom the rights of Roman citizenship had been conferred, and Sulla was compelled to flee to his camp at Nola in Campania. There, finding the soldiers full of enthusiasm, he resolved to lead them against the pseudo-government at Rome. The Marian party was overthrown and Marius fled to Africa. Sulla embarked for the East B.C. 87 and was away four years, but finally forced Mithridates to sue for peace, and returned to Italy B.C. 83. Marius was now dead, but his party was strong in numbers and again in revolt; yet before the close of B.C. 82 the Marian party in Italy was utterly crushed. In Spain, however, it held out under Sertorius (q.v.). Sulla caused himself to be appointed dictator, an office which he held until B.C. 79. Then followed the fearful period of the *proscriptions* (B.C. 81)—a virtual 'reign of terror' throughout Italy, the object of which was to extirpate the Marian party. His dictatorship was signalized by the framing of a series of laws the design of which was to restore the ancient power of the senate and the aristocracy. Sulla spent his last years at his estate at Puteoli, his death being hastened by debaucheries. Consult: Beesly, *The Gracchi, Marius, and Sulla* (New York, 1878).

SULLIVAN, Alexander Martin (1830-84). An Irish nationalist, born at Bantry. In 1853 he went to Dublin to become an artist and afterwards took up journalism. As editor of the *Nation*, the exponent of constitutional agitation, he became a formidable opponent of the Fenian conspiracy. In 1874 he was returned to Parliament as a Home-Ruler from the County of Louth, and from Meath in 1880. He was called to the Irish bar in 1876, and to the English bar in the following year, whereupon he discontinued his work for the *Nation* and went to England to practice law. He published *The Story of Ireland* (1870), *New Ireland* (1877), *A Nutshell History of Ireland* (1883).

SULLIVAN, Sir Arthur Seymour (1842-1900). A distinguished English composer. He was born in London of Irish parents. Sir George Smart accepted him as one of the children of the Chapel Royal, and during the choristership he wrote several anthems. His earliest published composition was a song "O Israel" (1855). In 1856, at the age of fourteen, Sullivan succeeded in obtaining the Mendelssohn scholarship, then recently established, and while still holding this scholarship he entered the Royal Academy of Music. In 1858 he went to Leipzig, where he studied at the Conservatory. His famous incidental music to Shakespeare's *Tempest* was his last work at the Conservatory, and was first heard in England in 1862, a few days after his arrival in the country. After holding organ appointments at Saint Michael's and at Saint Peter's he was appointed professor of the pianoforte and ballad-singing at the Crystal Palace School of Art, after which he gave a course of lectures on the theory and practice of music at the South Kensington Museum. His first great success in composition was his "Orpheus with His Lute," which was soon followed by "The Lost Chord." He was meanwhile engaged on more serious work, and in 1864 the cantata *Kenilworth* was produced. Then came the *Symphony in E* (1866), the *Overture In Memoriam* (1866), *The Prodigal Son* (1869), *Light of the World* (1873), *The Martyr of Antioch* (1880), *The Golden Legend* (1886), and the grand opera *Ivanhoe* (1891). He is held in greatest repute, however, for his light opera compositions, a form of writing into which he stumbled by the merest accident. The financial difficulties of the widow and family of a well-known artist on the staff of *Punch* caused the friends of the deceased to organize a 'benefit' for which F. C. Burnand and Sullivan promised to collaborate in a musical piece. *Box and Cox* was the result, and in seven days it was written, learned, rehearsed, and performed. The *genre* thus created became the field in which he achieved greatest success in collaboration with W. S. Gilbert. Besides those mentioned his dramatic works are: *The Contrabandista* (1867), afterwards enlarged as *The Chieftain* (1894), *Thespis* (1871), *Trial by Jury* and *The Zoo* (1875), *The Sorcerer* (1877), *H. M. S. Pinafore* (1878), *Pirates of Penzance* (1880), *Patience* (1881), *Iolanthe* (1882), *Princess Ida* (1884), *The Mikado* (1885), *Ruddigore* (1887), *The Yeomen of the Guard* (1888), *The Gondoliers* (1889), *Haddon Hall* (1892), *Utopia* (1893), *The Grand Duke* (1896), *The Beauty Stone* (1898), *The Rose of Persia* (1899), and *The Emerald Isle* (1901). In 1883 he was knighted by Queen Victoria. His music is essentially lyric in quality, and he was exceptionally fluent in melody as well as a master of dainty orchestration, in which latter respect he perhaps has never been excelled. His early training in the school of English church music left its imprint on all his sacred compositions. His anthems are distinguished by their pure melody and dignified harmony. His hymn-tunes are sung universally, and of these not the least important is his fine martial setting of "Onward, Christian Soldiers." He died in London.

SULLIVAN, Francis Stoughton (1719-76). An Irish jurist, born at Galway. He was educated at Trinity College, Dublin, where he gained a fellowship at the very early age of nineteen. He remained at Dublin until in 1750 he was made regius professor of law in the university and in 1761 professor of feudal and English law. He was a jurist of great distinction and his one important work, *An Historical Treatise on the Feudal Law* (1772), was long held in high favor.

SULLIVAN, James (1744-1808). An American jurist and politician, born in Berwick, Me.

He was admitted to the bar, and in 1770 was appointed King's attorney. In 1775 he was a member of the Massachusetts Provincial Congress, and was one of three commissioners dispatched on a secret mission to Ticonderoga. From 1776 to 1782 he was a judge of the Superior Court, and in 1784-85 a Massachusetts delegate to the Continental Congress. For many terms he was a member of the State Legislature, in 1787 was a member of the executive council, a probate judge, and from 1790 to 1807 was Attorney-General. In 1807 and 1808 he was elected Republican Governor of Massachusetts. He published *Observations on the Government of the United States* (1791), *The Altar of Baal Thrown Down* (1795), *Impartial Review of the Causes of the French Revolution* (1795). Consult the *Life* by T. C. Amory (Boston, 1859).

SULLIVAN, JOHN (1740-95). An American soldier, prominent in the Revolutionary War. He was born at Berwick, Me., removed to Durham, N. H., and there practiced law. In June, 1775, he was appointed brigadier-general by Congress. During the siege of Boston, with General Greene, he commanded the left wing under General Lee, and on June 4, 1776, was placed in command of the army in Canada, whence, after being badly defeated at Three Rivers, he retreated with great skill to New York. On August 10th he became a major-general, and on the 27th served with distinction at the battle of Long Island (q.v.), during which he was taken prisoner. He was exchanged and served in the battles of Trenton, Princeton, Brandywine, and Germantown. In 1778 he was sent with a large force to act with D'Estaing against Newport, but the plan being abandoned, after decisively defeating the English at Butt's Hill on August 29th, he withdrew from Rhode Island. In 1779 he marched into western New York, and effectually chastised the Iroquois, defeating them and their Tory allies at Newton (Elmira) on August 29th. Resigning from active duty late in 1779, he served in Congress in 1780-81, was Attorney-General of New Hampshire from 1782 to 1786, was President of the State from 1786 to 1789, and was United States district judge from 1789 to 1795. Consult his *Life* by Peabody in Sparks, *American Biography* (series 2, vol. iii.); Amory, *The Military Services and Public Life of General John Sullivan* (Boston, 1868); and *Journals of the Military Expedition Against the Six Nations* (Auburn, N. Y., 1887).

SULLIVAN, JOHN LAWRENCE (1858—). An American prize-fighter, born in Boston, Mass. In 1880 he defeated George Rooke, and two years afterwards he beat Ryan in nine rounds. In 1887 he fought a draw with Cardiff; in 1888 fought a draw with Mitchell at Chantilly, near Paris; and in the next year, in Mississippi, in a seventy-five round fight, defeated Kilrain, winning the American championship and a diamond belt offered by a sporting paper. In 1892 he met Corbett at New Orleans and was defeated in the twenty-first round, thereby losing the championship title. In 1896 he was defeated by Sharkey in three rounds.

SULLIVAN, THOMAS BARRY (1820?-91). A British tragedian, born in Birmingham. He was brought up in Cork, where he made his appearance on the stage before 1840. He joined the company of the Theatre Royal, Edinburgh, and remained there several seasons, advancing rapidly in his profession. In 1852 he appeared at the Haymarket Theatre, London, in Hamlet, the part in which he was on the whole most successful, though his Beverley in *The Gamester* was very highly praised. Consult Lawrence, *Barry Sullivan: A Biographical Sketch* (1893).

SULLIVAN, THOMAS RUSSELL (1849—). An American novelist and dramatist, born in Boston. He was educated at the Boston Latin School, passed the years 1870-73 in Europe, was then for fifteen years connected with a firm of Boston bankers as clerk and cashier, and after 1888 devoted himself to literature. He wrote *Roses of Shadow* (1885); *Day and Night Stories* (two series, 1890 and 1893); *Tom Sylvester* (1893); *Ars et Vita* (1898); *The Courage of Conviction* (1902); and several plays, of which the more noteworthy are *The Catspaw* (1881), a dramatization of *Dr. Jekyll and Mr. Hyde* (1886), and *Merely Players* (1886).

SULLIVAN'S ISLAND. An island at the entrance to Charleston Harbor, the site of Fort Moultrie (q.v.).

SULLIVANT, WILLIAM STARLING (1803-73). An American botanist, the founder of American bryology. He was born in Franklinton, Ohio, near Columbus, studied in Kentucky and in Ohio University, and in 1823 graduated at Yale. In 1840 he published a *Catalogue of Plants in the Vicinity of Columbus, Ohio*, and thereafter specialized in the cryptogamous plants. *Musci Alleghanienses* (1845) was followed in 1846 and 1849 by contributions to the *Memoirs* of the American Academy of Sciences "On the Bryology and Hepaticology of North America," and by a valuable addition to Gray's *Manual* on the mosses of the Northern United States, published separately in 1856 as *The Musci and Hepaticæ of the United States East of the Mississippi River*. In the same year, with the help of Lesquereux, he published *Musci Boreali-Americani Exsiccati*. *Icones Muscorum*, containing 129 valuable copper plates, is probably Sullivant's greatest work. At the time of his death he was at work on a *Manual of Mosses*.

SULLY, JAMES (1842—). An English psychologist, born at Bridgewater, Somersetshire. He was educated at Independent College, Taunton, Regent's Park College, London, and at the universities of Göttingen and Berlin. Until 1892 he served as lecturer in the College of Preceptors, London, and in that year became professor of the philosophy of mind and logic in University College, London. Sully published both general treatises and special studies in psychology, the most important being: *Outlines of Psychology, with Special Reference to the Theory of Education* (1884; 2d ed. 1885); *Elements of Psychology* (1886); *The Human Mind: A Text-Book of Psychology* (1892); *Studies of Childhood* (1895); and *Essay on Laughter: Its Forms, Its Causes, Its Development, and Its Value* (1902). Sully became known as one of the most eminent of modern English psychologists; his work carries on the best traditions of the English school, but is characterized by its breadth and careful recognition of the development of psychological science on the Continent.

SULLY, sụ'lē', MAXIMILIEN DE BÉTHUNE, Duke de (1560-1641). The great Minister of

Henry IV. of France. He was born at Rosny, near Mantes, the second son of François, Baron de Rosny. He belonged to a Protestant family and was educated with the young Henry at the Court of Navarre. This was the beginning of a friendship and a loyal service that continued until Henry's death. He escaped the Massacre of Saint Bartholomew, accompanied Henry in his flight from the French Court (1576), shared in the campaigns against the Catholic League, distinguishing himself especially at Coutras (1587), and became Henry's wisest and most trusted adviser. He urged Henry's acceptance of Catholicism to save the crown. The misgovernment of the preceding years and the anarchy of the wars of religion had almost ruined France, and Sully, made Minister of Finance in 1597, and chief intendant in 1599, set himself thoroughly to reform the administration. He made a tour through the chief provincial districts, armed with absolute authority, personally examined the accounts, dismissed or suspended delinquents, and largely replenished the treasury with the ill-gotten wealth which he compelled them to disgorge. Little by little he brought the affairs of the country into an orderly state. From 1597 to 1609 he trebled the income of the State. His indefatigable activity was not confined to the department of finance; he practically was in supreme charge of the various other branches of the administration, promoted agriculture, encouraged export trade, and constructed roads, bridges, and causeways. He was made grand master of artillery in 1601, and in 1606 was created Duke de Sully. Sully was not popular. His single-minded service of the King made him disliked by the people for his supposed severity. The Catholics hated him for his religion; the Protestants for his invariable refusals to sacrifice the smallest jot of his master's or the country's interest for their sake. At Henry's death he was forced to resign his offices and lived in comparative retirement. Sully wrote *Mémoires des sages et royales économies d'état, domestiques, politiques et militaires, de Henri le Grand*, a wearisome and disorderly collection of writings in the form of a narrative addressed to himself by his secretaries. It is through these volumes that we are made acquainted with the 'great design' of Henry for the federation of Europe, a design the genuineness of which has been the subject of much controversy. The edition in Michaud and Poujoulat, *Nouvelle collection des mémoires pour servir à l'histoire de France*, is from the original. Consult Lavisse, *Sully* (Paris, 1880).

SULLY, Thomas (1783-1872). A portrait painter of the early American school. Born at Horncastle, Lincolnshire, England; he was brought by his parents, who were actors, to Charleston, S. C., in 1792. In 1806 he removed to New York, and in 1809 he went to London, where he completed his studies begun in America under Benjamin West. Two years later he returned to America and settled in Philadelphia. Among his best known portraits are those of Commodore Decatur in the City Hall, New York; General Lafayette at Independence Hall, and George Frederick Cooke at the Pennsylvania Academy of Fine Arts, Philadelphia; Thomas Jefferson (1821) at the Military Academy, West Point; and portraits of Charles Kemble, Frances Anne Kemble, and Rembrandt Peale, James Madison, Andrew Jackson, and John Marshall, in the Corcoran Gallery, Washington. Consult his "Recollections of an Old Painter," in *Hours at Home* (1869).

SULLY-PRUDHOMME, sụ'lē' prụ'dôm', René François Armand (1839—). A French poet, born in Paris. He was educated for the law, and was a student of science and philosophy. In 1865 he published *Stances et poèmes*, which won the praise of Sainte-Beuve for their delicate elegiac sentiment. Encouraged by this success, he devoted himself wholly to poetry. In 1866 appeared *Les épreuves*, a work in which the sadness of unbelief is poignantly expressed. *Les solitudes* (1869) and a rhymed translation of the first book of Lucretius (1869) foreshadow by their depth his great philosophical poems *La justice* (1878) and *Le bonheur* (1888). These two last-mentioned poems are among the greatest efforts of French poetry since Victor Hugo and Lamartine. *Impressions de guerre* (1870) deal with some of the phases of the Franco-German War. *Les destins* (1872), *Vaines tendresses* (1875), and *Le prisme* (1886) are less philosophic and more personal. Sully-Prudhomme entered the Academy in 1881, and in 1901 received one of the Nobel prizes in recognition of the lofty qualities of his poetry. He devoted a portion of this to establishing an annual award for excellence among the younger French poets. His verses are thoughtful and often melancholy. Sensitively open to all impressions, he is singularly temperate in expression. This quality of reserve is particularly noticeable in his expression of the sadness which is his usual mood.

Consult: Brunetière, *Poésie lyrique*, vol. ii. (ib., 1894); id., *Littérature contemporaine* (2d ed., ib., 1895); Lemaître, *Les contemporains*, vols. i., iv. (ib., 1896); Gaston Paris, *Penseurs et poètes* (ib., 1897).

SULPHOCYANIC ACID, or Thiocyanic Acid, HCNS. A powerful organic acid analogous in its composition to the well-known cyanic acid (q.v.), HCNO, from which it differs in containing sulphur instead of oxygen. *Sulphocyanates*, i.e. salts of sulphocyanic acid, may be obtained by the direct action of sulphur on cyanides (i.e. salts of hydrocyanic acid). Thus, potassium sulphocyanate may be obtained by boiling a solution of potassium cyanide with sulphur. Free sulphocyanic acid may be prepared by decomposing barium sulphocyanate with sulphuric acid, and distilling the aqueous acid thus obtained over warm anhydrous chloride of calcium. The acid is thus obtained in the form of a volatile liquid with a characteristic pungent odor. Pure sulphocyanic acid may be preserved for some time if kept in the cold. At ordinary temperatures it rapidly polymerizes, forming an amorphous yellow substance. Several of the sulphocyanates are extensively used as mordants in certain dyeing processes. The principal commercial source of the salts is found in the manufacture of coal gas. The products formed during the destructive distillation of coal include ammonia, cyanogen, a certain amount of ammonium cyanide, and certain compounds of sulphur. In course of the purification of the gas, these by-products are brought into contact with moist ferric oxide for the purpose of freeing the gas from deleterious sulphur compounds. The sul-

phur is thus retained partly in the free state, partly as iron sulphide, and by combination with the ammonium cyanide present yields *ammonium sulphocyanate*, which may be dissolved out of the reacting mixture with water. Ammonium sulphocyanate itself may be used for the preparation of hydrazine. Usually it is transformed into the sulphocyanate of copper, from which, in turn, the useful *sulphocyanate of barium* is obtained by the action of baryta. The *sulphocyanate of aluminum*, another useful salt of sulphocyanic acid, may be obtained by the action of aluminum sulphate on the sulphocyanate of barium. Most of the sulphocyanates are soluble in water. *Sulphocyanate of mercury* may be obtained by the action of mercuric nitrate on the sulphocyanate of ammonium. It decomposes on moderate heating, the resulting mass, externally yellow, but black within, assuming a large size and often a most fantastic shape. This sulphocyanate is the principal ingredient of the well-known toy known as 'Pharaoh's serpents.' Each serpent consists of a little cone of tinfoil, filled with the salt. On lighting the cone at the apex, there begins to issue from it a thick serpent-like coil, which continues twisting and increasing in length to an extraordinary degree.

Like cyanic acid (q.v.), sulphocyanic acid furnishes a simple example of the phenomenon known as *tautomerism*. The two constitutional formulas corresponding to the acid, as deduced from a study of its two different series of derivatives, are as follows:

$$N \equiv C - S - H \quad \text{and} \quad H - N = C = S$$

The two imaginary compounds corresponding to these formulas, but in reality represented by only one acid, are called, respectively, sulphocyanic acid and iso-sulphocyanic acid (or thiocyanic acid and iso-thiocyanic acid).

SULPHONAL $(CH_3)_2C(SO_2C_2H_5)_2$. A white crystalline compound used as a hypnotic. It is prepared by the action of acetone on mercaptan (q.v.) and the oxidation of the resulting product by permanganate of potassium. It is sparingly soluble in water and alcohol and is best administered with hot milk. It is employed as a substitute for chloral, over which it has the advantage of exercising no depressing action on the heart. It is, however, a poisonous substance and has been known to produce serious functional disturbances and eruptions on the skin. It is sometimes administered in conjunction with a similar compound, known as trional (q.v.).

SULPHOVINIC ACID. Same as ethyl hydrogen sulphate, or ethyl sulphuric acid. $C_2H_5.H.SO_4$. See ALCOHOL.

SULPHUR (Lat. *sulphur*, *sulfur*, sulphur; possibly connected with Goth. *swibls*, OHG. *swebal*, Ger. *Schwefel*, AS. *sweft*, sulphur). A non-metallic element that has been known since ancient times. Owing to the fact that it burns readily, it was called *brennestone* or *brimstone*, and was regarded by the alchemists as the principle of combustibility, representing the alterability of metals by fire. It occurs in the uncombined state, though usually contaminated with clay, bitumen, and other impurities, and sometimes with traces of arsenic, selenium, tellurium, etc., usually in the vicinity of volcanoes and hot springs. Its compounds, especially those with metals (sulphides), are of common occurrence, and include *chalcopyrite* or copper-iron sulphide, *cinnabar* or mercury sulphide, *galena* or lead sulphide, *pyrite* or iron sulphide, the arsenic sulphides or *realgar* and *orpiment*, *sphalerite* or zinc sulphide, *stibnite* or antimony sulphide. In combination with metals and oxygen (sulphates), sulphur occurs in such minerals as *anglesite* or lead sulphate, *barite* or barium sulphate, *celestite* or strontium sulphate, *chalcanthite* or copper sulphate, *gypsum* or calcium sulphate, and *kieserite* or magnesium sulphate. Volcanic gases generally contain sulphur in the forms of sulphur dioxide and sulphureted hydrogen, and compounds containing sulphur are found in certain organic materials, such as the volatile oils of mustard and garlic, hair, wool, bile, and albuminous substances. It is generally believed that native sulphur has been formed by the action of sulphur dioxide on hydrogen disulphide. Sulphur may also be obtained by decomposing certain mineral sulphides, such as pyrite. The commercial article is usually obtained by purifying native sulphur by fusion, or by distillation, and is produced largely in Sicily, where it occurs mixed with celestite, gypsum, limestone, and marl. The ore, after being carefully hand-picked, was formerly heated in heaps from which the liquid sulphur collected in a trough at the bottom, whence it was ladled out; but as this process was very wasteful, kilns came into use, in which the sulphur ore was piled and ignited at the bottom; the heat penetrated slowly into the mass, and as the sulphur gradually melted it ran to the bottom of the kiln, where it was collected and then cast into molds. Sulphur may also be extracted from ores by using a solvent such as carbon disulphide, from which it is then separated by distillation. Crude commercial sulphur usually contains about 3 per cent. of earthy impurities, which may be removed by distillation, in which case the sulphur is first melted and then heated to the boiling-point, the vapor of sulphur then passing into a large chamber, where it condenses and falls to the floor in the form of a light yellow crystalline powder commonly known as *flowers of sulphur*. This is cast into slightly conical wooden molds, when it is known as *roll sulphur* or *brimstone*, and sometimes it is allowed to cool in the chamber, when it is obtained in large crystalline masses called *block sulphur*.

Sulphur (symbol, S; atomic weight, 32.07) occurs in several allotropic modifications. One of these is a brittle solid that crystallizes in the rhombic system, but that on heating passes into transparent yellowish-brown needles of the monoclinic system. Both of these forms are soluble in carbon disulphide. The modifications of sulphur that are insoluble in carbon disulphide include plastic, amorphous, yellow, and black sulphur. There is a variety of sulphur that is soluble in water. This is known as *colloidal sulphur* and is obtained by passing hydrogen disulphide into an aqueous solution of sulphur dioxide. Sulphur has a specific gravity of about 2.03, and melts variously from 111° to 115° C. It is a poor conductor of heat and electricity. The element itself is extensively used in the arts and manufactures, as in making gunpowder and matches, and in medicine.

Sulphur combines with oxygen to form a dioxide (SO_2) and a trioxide (SO_3), which in turn combine with water to form sulphurous and sulphuric acids (H_2SO_3 and H_2SO_4 respectively).

It also forms a sesquioxide (S_2O_3) and a heptoxide (S_2O_7); but these are unimportant. Sulphur dioxide, or sulphurous anhydride, was known to the ancients, and Homer mentions the fact that the fumes from burning sulphur were used for fumigation, while Pliny says that such fumes were employed for purifying cloth. It is readily formed by burning sulphur in the air, and also by the action of certain metals, such as copper, on sulphuric acid. It is a colorless gas with a suffocating odor and is freely soluble in water, forming sulphurous acid. The gas is used as a bleaching agent, as a disinfectant, and as an antiseptic, serving to prevent the putrefaction of meat and to stop fermentation. It is also used in the sulphuring of wine. Its compound with water, known as sulphurous acid (H_2SO_3), combines with bases to form a series of salts which are known as sulphites. *Sulphur trioxide*, or sulphuric anhydride, is formed when a mixture of sulphur dioxide and oxygen is passed over platinum sponge, or by the distillation of fuming sulphuric acid. It is a colorless mobile liquid that solidifies in the form of long transparent prismatic crystals which melt at 14.8° C. The liquid boils at 46° C. It is very acrid and chars paper, wood, and organic matter generally. When thrown into water it dissolves with a hissing sound and evolves a large amount of heat, forming sulphuric acid (q.v.). Under the name of *crystallizable sulphuric acid*, it is used in the manufacture of coal-tar colors, such as alizarin, and in the purification of ozokerite. With hydrogen and oxygen sulphur forms a series of acids including, besides those already mentioned, the following: *thiosulphuric* or *hyposulphurous acid* ($H_2S_2O_3$), which is described elsewhere; *hydrosulphurous acid* (H_2SO_2), a powerful reducing agent discovered by Schützenberger and prepared by the action of metallic zinc on acid sodium sulphite; *persulphuric acid* (HSO_4), obtained in a combined form by the electrolysis of a strong solution of acid potassium sulphate; *pyrosulphurous acid* ($H_2S_2O_5$), whose potassium salt is formed when sulphur dioxide gas is passed into a hot aqueous solution of potassium carbonate; *pyrosulphuric acid* ($H_2S_2O_7$), formed by the direct union of sulphur trioxide and sulphuric acid; *dithionic acid* ($H_2S_2O_6$), whose manganese salt is formed by the action of sulphur dioxide on manganese dioxide; *trithionic acid* ($H_2S_3O_6$), whose potassium salt is formed by the action of flowers of sulphur on a warm solution of acid potassium sulphite; *tetrathionic acid* ($H_2S_4O_6$), whose sodium salt is formed by the action of iodine on sodium hyposulphite; *pentathionic acid* ($H_2S_5O_6$), formed, along with free sulphur, by the action of sulphur dioxide on aqueous sulphureted hydrogen.

Sulphur combines with hydrogen to form a disulphide (sulphureted hydrogen, q.v.) and a persulphide, of which the former is well known. The persulphide (probably H_2S_5) is an oily yellow liquid which is prepared by pouring an aqueous solution of an alkaline polysulphide into excess of a solution of about equal parts of concentrated hydrochloric acid and water. It has the property of bleaching organic coloring matters, and reduces the oxides of gold and silver with great rapidity. With carbon sulphur combines to form a disulphide (CS_2), which is described in a special article. (See CARBON DISULPHIDE.) With chlorine sulphur combines to form a monochloride (S_2Cl_2), a dichloride (SCl_2), and a tetrachloride (SCl_4), of which the most important is the monochloride. This is prepared by passing dry chlorine gas over melted sulphur and distilling off the chloride from the excess of sulphur. It is an amber-colored liquid that fumes strongly in the air, and possesses a penetrating odor. A saturated solution of sulphur in the monochloride is used in vulcanizing rubber goods.

SULPHUR, MEDICAL USES OF. Sulphur is used in medicine both internally and externally. It is prepared from crude sulphur by sublimation, washing, and precipitation. Taken by the mouth sulphur is in medicinal doses a mild laxative, producing a soft stool, which slips by strictures of the rectum, piles, and fissures with little discomfort. It is, therefore, used in these conditions. Sulphur is particularly valuable for chronic rheumatism, either taken in the form of mineral waters containing this element, or externally by means of sulphur baths. The latter are employed in various chronic skin diseases, of obstinate type, such as psoriasis, lichen, and eczema. (See BATH and MINERAL WATERS.) Calcium sulphide is of value in all cases where pus is about to form, as when successive crops of boils appear, or in acne pustulosa.

The external uses of sulphur are mostly confined to affections of the skin and as a parasiticide. It is only active when used in the form of an ointment. For the itch (q.v.) sulphur ointment is a specific. It is also a favorite remedy for ringworm (tinea, q.v.).

SULPHURETED HYDROGEN, HYDROGEN SULPHIDE, or HYDROSULPHURIC ACID, H_2S. A gaseous acid compound of sulphur and hydrogen, known since the sixteenth century, but first carefully investigated by Scheele in 1777. It occurs uncombined in certain mineral waters and is formed in the decomposition of albuminous substances containing sulphur. It also occurs as a product of transformation of gypsum (calcium sulphate) and other metallic sulphates and is a constituent of volcanic exhalations. But whatever its origin, it does not long remain unchanged in the air, being oxidized with the greatest ease. The usual method of preparing the gas consists in causing sulphuric or preferably hydrochloric acid to act on ferrous sulphide. The following rule usually holds good: Sulphureted hydrogen is formed by the action of acids on the sulphides of those metals (e.g. iron, zinc, manganese, calcium, magnesium, sodium, potassium, etc.) which can directly decompose the acids with liberation of hydrogen. Sulphureted hydrogen is a colorless gas, somewhat heavier than air, soluble in water and more so in alcohol, the solutions reddening blue litmus paper. Mixed with 1½ volumes of oxygen and ignited, it explodes, the products of the reaction being water vapor and sulphur dioxide (SO_2). Under the influence of cold and pressure, sulphureted hydrogen condenses to a colorless mobile liquid. Sulphureted hydrogen is very poisonous, and even small proportions of it in the air are dangerous. The presence of free sulphureted hydrogen may be demonstrated by means of a strip of filter-paper soaked with a solution of lead acetate, the paper turning brown or black, owing to the formation of lead sulphide. Chlorine and

iodine decompose sulphureted hydrogen, and this is why the odor of the latter is readily destroyed by bleaching-powder. Sulphureted hydrogen is used in the manufacture of certain metallic sulphides, for the purification of sulphuric acid, and extensively in analytical chemistry. The sulphureted hydrogen produced in certain industrial processes is utilized by burning it and transforming the resulting sulphur dioxide either into sulphuric acid or into free sulphur.

SULPHURIC ACID, H_2SO_4. A well-known acid compound of hydrogen, sulphur, and oxygen. When pure and free from water, it is a colorless, oily liquid of specific gravity 1.84 (approximately) at 0° C. While it may readily be undercooled, it solidifies normally at 6.79° C. (44.3° F.). At about 290° C. (554° F.) it begins to boil, breaking up into sulphur trioxide and water vapor, and as some of the latter is retained by the boiling acid, the temperature rapidly rises to about 338° C. (640° F.). It is highly hygroscopic, absorbing about 30 per cent. of its weight of water. It readily chars organic matter, and is poisonous, not only on account of its powerful corrosive action, but also on account of a specific effect on the blood. Chemically it is a dibasic acid, either one or both of its hydrogen atoms being replaced by metals, with the formation, respectively, of either acid or neutral salts (sulphates). Its chemical constitution is generally assumed to be represented by the formula H — O — S — O — O — O — H. By adding to it a little water, it may be caused to form the hydrate $H_2SO_4.H_2O$, which crystallizes out when the mixture is cooled and may then be readily isolated from the mother-liquor by suction. Glass bottles containing commercial sulphuric acid often burst in winter, owing to the separation of crystals of this hydrate, whose melting-point is about 8° C. (about 46° F.), and which decomposes into sulphuric acid and water above 205° C. (about 370° F.). If pure sulphuric acid is mixed with water in the proportion of 49 parts of the former to 18 parts of the latter, another well-defined hydrate is formed, having the composition $H_2SO_4.2H_2O$.

The term 'sulphuric acid,' however, as technically and commercially understood, seldom if ever refers to the actual monohydrate or to any of the other recognized hydrates of sulphur trioxide.

It refers either to a series of solutions of the monohydrate in water or to a series of solutions of sulphur trioxide in the monohydrate. ($H_2SO_4 + SO_3$.) The first series are known commercially as 'chamber acid'—'oil of vitriol'—'concentrated acid' or in terms of their specific gravity as indicated by a hydrometer scale, as 60° Baumé acid, 144° Twaddell acid and so forth. The second series are termed 'fuming' or Nordhausen acids, and are always estimated alkali-metrically according to the percentage of free sulphur trioxide contained.

Technically, therefore, 'sulphuric acid' might be considered to be the generic name of a series of solutions of sulphur trioxide (SO_3) in water, some of which solutions are distinguished by variations of properties which occur uniformly with uniform percentage mixtures of sulphur trioxide and water and are therefore chemical hydrates of sulphur trioxide—most of which are, however, merely solutions of convenient strength for use in the arts.

The manufacture of sulphuric acid is one of the greatest chemical industries. The processes involved include the production of sulphur dioxide, the transformation of this into sulphur trioxide, and the transformation of the trioxide into sulphuric acid. Of these, the oxidation of the dioxide is the most important, the dioxide itself being readily produced by burning sulphur, mineral sulphides, or sulphureted hydrogen, with free access of air, the resulting gases, technically termed 'burner-gas,' including from 5 to 8 per cent. of the dioxide (the remainder is constituted by the nitrogen and excessive oxygen of the air and by impurities). The two processes devised to effect the oxidation of the dioxide are alike catalytic in their action, in so far as the

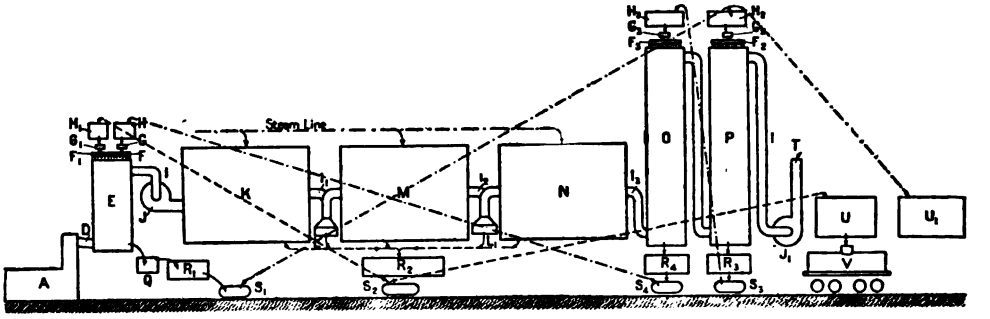

DIAGRAM SHOWING CHAMBER PROCESS FOR MAKING SULPHURIC ACID.

In the figure, A is a bench of pyrites burners, niter oven, etc. The burner-gas is conducted through pipe D to the Glover tower, E, where it meets the dilute acids and oxides of nitrogen. The fan J carries the gases through the pipe I to the first chamber, K, where oxidation of the sulphur dioxide takes place in presence of water vapor supplied by the steam-line shown above the chambers, thence to the second and third chambers, M and N, through the flues I_1 and I_2 and surface condensers L and L_1. The acid drained from the bottom of each chamber and the condensers is collected in the tank R_2.

The pump S_2 delivers this acid to the tank H_1, over the Glover tower, or to the storage tank U, whence it goes to the tank-car V. The strong acid coming from the Glover tower is collected in cooler Q and tank R_1 and is delivered by the pump S_1 to the tank H_2 over the second Gay-Lussac tower, P, and to the storage tank U_1. The gases from the last chamber, N, are conducted through the pipe I_3 to the first Gay-Lussac tower, O, and thence to the second Gay-Lussac tower, P, their flow being maintained by the fan J_1. The exhausted gases pass to the atmosphere at T. The nitrous vitriol from the first Gay-Lussac tower is collected in the tank R_4 and is delivered by the pump S_4 to tank H over the Glover tower. The nitrous vitriol from the second Gay-Lussac tower, containing but little N_2O_3, is collected in the tank R_3 and is delivered by the pump S_3 to the tank H_3 over the first Gay-Lussac tower. In different works this scheme varies somewhat in detail, but not in its essential points.

substances used, while producing the required chemical reaction, remain themselves in the end unchanged. These two processes are termed, respectively, the chamber process and the contact process.

THE CHAMBER PROCESS. In the chamber process the burner gas is mixed in large lead chambers (and with more or less auxiliary apparatus) with nitric acid, or with the products of the action of sulphuric acid on sodium nitrate, the catalytic agent being probably nitrogen trioxide, and the following reactions probably taking place:

$$2SO_2 + N_2O_3 + H_2O + O_2 = 2SO_2(OH)(NO_2);$$
$$2SO_2(OH)(NO_2) + H_2O = 2H_2SO_4 + N_2O_3.$$

The nitrogen trioxide is thus entirely reproduced. In addition to the above principal reactions there are further reactions set up in the so-called Guy-Lussac and Glover towers, in which apparatus, respectively, the catalytic agent is recovered and made available (in the form of nitric acid) for further use. The principle of the chamber process, therefore, is the production of a dilute sulphuric acid by oxidizing a burner gas containing say 5 per cent. to 8 per cent. of sulphur dioxide in presence of water vapor by the means of nitric acid in suitable apparatus in such a way that the nitric acid is practically recovered for further use. This recovery, however, is rarely complete—a certain mechanical loss being unavoidable. The strongest acid which can be produced by the chamber process will correspond to from 50 per cent. to 60 per cent. of sulphur trioxide. Stronger acids must be produced by driving off the contained water by heat or by isolating the acid by freezing. It is thus possible to produce the concentrated acid (oil of vitriol) of commerce, containing from 93.5 to 97 per cent. of pure sulphuric acid; also distilled acid, containing up to 95.5 per cent. of H_2SO_4; but the anhydrous can only be isolated by freezing.

THE CONTACT PROCESS. In the contact process the method of production is directly synthetical, and acids of any desired strength may be made in one operation. In this process the burner gas must be first rendered absolutely free from everything other than sulphur dioxide, oxygen, and inert nitrogen, the usual impurities of burner gas, such as dust, moisture, arsenic, selenium, etc., derived from the raw material used, seriously interfering with the process. After purification, the gas is passed through a substance possessing the faculty of causing sulphur dioxide to oxidize into sulphur trioxide, without apparently suffering any change whatever in its own condition. This contact must be brought about under conditions as to temperature according to the substance used. The contact substances used are finely divided platinum in various forms, such as platinized asbestos and pumice, etc., crusts formed of platinum and some soluble sulphate, ferric oxide, cupric sulphate, diatomaceous earth, etc. The transformation of sulphur dioxide into the trioxide takes place best between 200° and 450° C. (392°-842° F.). Above 450° C. the transformation grows incomplete, for at that temperature commences the dissociation of sulphur trioxide into dioxide and free oxygen—a dissociation which is complete at 900° C. The formation of sulphur trioxide having been attained, it simply remains either to condense it at the proper temperature in its crystalline condition or to absorb it in sulphuric acid or water until a solution of the required strength is obtained.

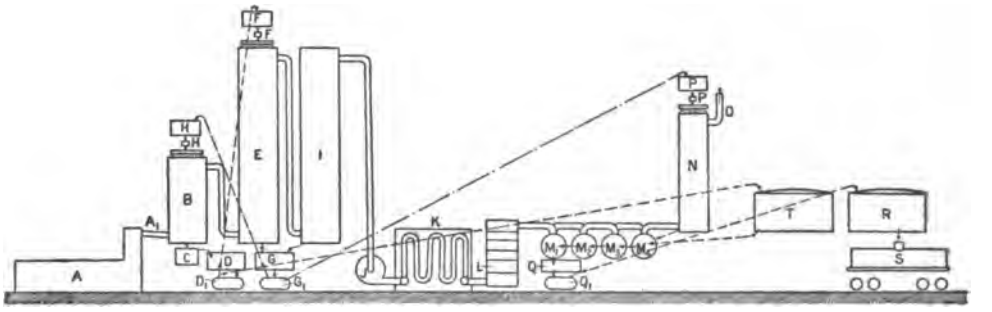

DIAGRAM SHOWING CONTACT PROCESS FOR MAKING SULPHURIC ACID.

A is a bench of pyrites burners. The burner gas passes through the flue A_1 to the first cleaning tower, B. Weak sulphuric acid is constantly flowing down this tower, becoming concentrated by the hot burner gas and absorption of the sulphur trioxide contained in the burner gas, and finally flows out at the bottom into the cooler C at a strength of from 62° to 64° Baumé. From the cooler C the strong acid passes to the tank D and is delivered by the pump D_1 to the storage tank T, or to the tank F over the second cleaning tower, E. A constant stream of strong sulphuric acid from the tank F is kept flowing down this tower. In this tower the burner gas coming from the top of B is further cleaned and dried by the action of the strong acid and then passes to the filter tower, I; the circulation of the gases through the train of apparatus is maintained by the fan J. Before entering the contact ovens, the mixed gases are reheated to the proper temperature for the combination of the sulphur dioxide and oxygen in the reheater, K.

The contact oven, L, consists of cast-iron rings with perforated shelves, or diaphragms, upon which is placed the contact mass.

The sulphur trioxide formed in the contact oven now passes through the absorption cylinders, M_1, M_2, M_3, M_4. These are cylindrical iron tanks connected in such a way that the gas passes from end to end, meeting the weak acid flowing in the opposite direction. Both the gas and the acid in M_1 are richest in sulphur trioxide, while in M_4 the gas and acid are weak. Sulphur trioxide is most readily absorbed by acid containing about 98% H_2SO_4. The strong acid, which is ready for the market as it comes from M_1, is collected in the tank Q and is delivered by the pump Q_1 to the storage tank, R.

The gases coming from the last absorption tank, M_4, contain still a small amount of unabsorbed sulphur trioxide. In order to recover this, the gases are passed through the tower N, which is supplied with strong acid which absorbs the last traces of sulphur trioxide. The nitrogen and oxygen remaining pass into the air through the pipe O. The tank car S receives acid for shipment from the storage tank, R.

USES OF SULPHURIC ACID. The uses of sulphuric acid in the arts are extremely varied and of the highest importance. It forms the basis of manufacture of nearly all the other acids and

salts. Nitric, hydrochloric, acetic, picric, phosphoric, oxalic, tartaric, citric, and stearic acids, chemical manures and fertilizers, are all prepared by the agency of sulphuric acid. It is also used in the metallurgy of copper, cobalt, nickel, silver, and platinum, as well as in the preparation of sheet iron and wire for galvanizing and tinning; in the preparation of phosphorus, bromine, iodine, potassium bichromate, ordinary ether, and various esters (q.v.), starch, glucose, sugar, and effervescent drinks; in the manufacture of parchment papers, cellulose, celluloid, high explosives, nitroglycerin, nitrobenzene, guncotton, smokeless powders, pyroxilene, etc.; in the manufacture of coal-tar colors and dyes; in dyeing, calico printing, and tanning; in refining mineral oils, tallow, benzene, and paraffin; in the preparation of the various sulphates, as those of ammonium, potassium, barium, magnesium, aluminum, iron, zinc, copper, mercury, atropine, hydroscyamine, morphine, quinidine, quinine, strychnine, and others, too numerous to mention and many of which have an extensive application in therapeutics.

HISTORY. Geber was the first to describe sulphuric acid as a spirit which can be produced from alum and which possesses solvent properties. From the year 1613 sulphuric acid was prepared by the apothecaries by burning sulphur with access of air in moist vessels. In 1666 the addition of a little saltpetre was introduced by Nicholas Lefèvre About 1740, at Richmond, near London, England, the first sulphuric acid works on a commercial scale were founded, producing oil of vitriol 'made by the bell' in contradistinction to that distilled from copperas. The birth of the modern method of sulphuric acid making, however, dates from Roebuck's installation of lead chambers in Birmingham in 1746, and his further installation at Prestonpans, in Scotland, in partnership with Garbett. As late, however, as 1800 the Prestonpans works only yielded 111 per cent. on the sulphur burned, with a consumption of 13 per cent. of nitrate of soda (modern practice would yield 300 per cent. of the acid on sulphur burned with a consumption of less than 3 per cent. nitrate of soda). The chambers at that time were about 14 feet long, 10 feet high, and 4 feet 10 inches wide. (They are now commonly 50 feet to 100 feet long, 20 feet to 25 feet high, and 20 feet to 30 feet wide.) In 1827 Gay-Lussac introduced his towers for the recovery of nitric acid. Another important step was the introduction, in 1859, by John Glover, of his denitrating and concentrating tower at the Washington Chemical Works, near Durham, in England. This completed the rational and economical method of manufacture known as 'the chamber process.' From that time on the history of the chamber process of manufacturing sulphuric acid has been largely one of minor improvements, economics, and investigations into the chemical reactions involved in the process.

In the meantime, however, as early as 1817, the catalytic action of platinum was discovered by Sir Humphry Davy, and this phenomenon was further investigated by Edmund Davy, Döbereiner, and others. In 1831 Peregrine Phillips, Jr., an acetic acid manufacturer, discovered and patented the application of the catalytic action of platinum to the production of sulphur trioxide. The matter remained dormant until 1848, when the Belgian Schneider claimed to have discovered in pumice stone a substance of great catalytic activity. From this time on the subject received the attention of many scientists in Europe. But it was not until the publication of the investigations of Clemens Winkler in Dingler's *Journal*, in 1875, that the foundation of a commercial contact process can be said to have been securely laid. Subsequent work by Hanisch and Schroeder, Messel and Lunge, and others, followed. Finally, about 1880, the matter was taken up by the Badische Anilin und Soda Fabrik in Germany, and this firm, after a long, costly, and obstinate struggle, brought the process to a commercial success. An output of 18,500 tons of sulphur trioxide by this firm in 1888 had been increased in 1890 to 116,000 tons. Other manufacturers also have made the contact process an established success, the different manufacturers working on slightly different methods or different contact materials. As yet, however, the only contact material of demonstrated commercial value is platinum in one or the other form or combination. In the United States the first contact plant was erected in 1899, at Mineral Point, Wis., by the New Jersey Zinc Company under the patents of Schroeder. This plant was almost immediately followed by others, all of which are in successful operation, and while this process cannot be said to have superseded the old chamber process, its advantages are such that its complete triumph is probably only a matter of time and improved methods.

BIBLIOGRAPHY. Until the publication of Georg Lunge's *Sulphuric Acid and Alkali* in 1879 (3d Eng. ed., London, 1903), the literature on this subject was confined entirely to the scientific journals and *Proceedings* of scientific societies. Consult also a lecture by Dr. Rudolf Kneitsch before the German Chemical Society, October 19, 1901, an English translation of which was published in the *Mineral Industry*, vol. x. Vols. vii., viii., ix., x. of the *Mineral Industry* also contain reports on "Progress in the Sulphuric Acid Industry."

SULPHURIC ETHER. See ETHER.

SULPHUROUS ACID (H_2SO_3). A colorless liquid containing about 6.4 per cent. of sulphurous anhydride (SO_2) and 93.6 per cent. of water. The gas is a valuable disinfectant and has been used for this purpose from the most ancient times. The gas is employed almost universally at the present day to disinfect buildings and rooms, although formaldehyde gas is gradually superseding it. Sulphurous acid is used as a spray or lotion in diphtheria and stomatitis, and is valuable as a wash for indolent ulcers and foul sores. It is an excellent remedy for ringworm. The acid is sometimes given internally to prevent abnormal fermentation in the stomach and intestines in certain varieties of dyspepsia, but its value is problematical, and there are many other drugs suitable for this condition whose action is certain. See DISINFECTANTS; FUMIGATION.

SULPHUR SPRINGS. The county-seat of Hopkins County, Texas, 79 miles east by north of Dallas, on White Oak Creek, and on the Saint Louis Southwestern and the Missouri, Kansas and Texas railroads (Map: Texas G 3). It has cotton gins, a cotton compress, cottonseed-oil mills, and manufactories of leather, brick and

tile, carriages and wagons, and lumber products. The water-works are owned by the municipality. Population, in 1890, 3038; in 1900, 3635.

SULPICIANS, sŭl-pĭsh'anz. A society of priests founded in 1641 by Jean Jacques Olier (q.v.) to educate candidates for the priesthood. It took its name from the parish of Saint-Sulpice in Paris, of which Olier was pastor. When the number of priests had increased beyond the needs of the parish, some took charge of a seminary; and this has since been their principal work. At the present time they have charge of the clerical seminaries in twenty-five dioceses of France. They came to Canada in 1642 and had a large share in the founding of the city of Montreal as a Christian colony; for a long time they did all the priestly work there, and still conduct the seminary. On the invitation of Bishop Carroll, they came to Baltimore in 1790 and took charge of the seminary founded there a year later; in 1808 they established another at Emmitsburg, the later Mount Saint Mary's College. They also have charge of the seminaries in the dioceses of New York, Boston, and San Francisco, and of the clerical students in the Catholic University at Washington.

SULPICIUS (sŭl-pĭsh'ĭ-ŭs) **SEVE'RUS** (c.363-c.410.) An ecclesiastical historian, born in Aquitaine. According to Paulinus (Ep. xxii.) he went to live at Primuliacum, a village near Toulouse, and about this time he seems to have taken monastic vows. He was a friend of Saint Martin, Bishop of Tours, whom he frequently visited, and whose life he wrote (*Vita S. Martini Turonensis*). His biography and his dialogues are of great historical value. The most important of Sulpicius's other writings is his *Historia Sacra*, composed about 403. This book was for a long time used as a text-book for history in the schools of Europe (till c.1656). There is an English version of his writings, by Alexander Roberts, in *Nicene and Post-Nicene Fathers* (vol. xi., 2d series, New York and Oxford, 1894).

SULTAN. A breed of small fowls, derived from Turkey, and kept for their beauty of plumage and docility as pets.

A SULTAN COCK.

SULTAN (Ar. *sulṭān*, emperor, empire, from *saliṭa*, to be imperious). A common title of Mohammedan princes since the time of the Ghaznivid Mahmud (997-1030). It is given, *par excellence*, to the ruler of Turkey, who takes the name *sultan khan*, 'reigning sultan,' or sultan of sultans. It is also given to the princesses of the royal house, and the Sultan's mother is called *valide sultan;* the mother of his first-born son is called *hasseki sultan*. In English a feminine form *sultana* is usually employed for women.

SULTE, sŭlt, BENJAMIN (1841—). A French-Canadian author, born at Three Rivers, in the Province of Quebec. Taken from school at the death of his father, who perished at sea, Sulte pushed his way through various employments into journalism and into the service of the Government as translator. His most solid prose work is the *Histoire des Canadiens-Français* (8 vols., 1882-84), which was followed by *Histoire de Saint François-du-Lac* (1886) and *Pages d'histoire du Canada* (1891). Sulte is also well known for his songs in *Les Laurentiennes* (1870) and *Les chants nouveaux* (1880).

SULU, sōō-lōō', or JOLÓ. The capital of the island and archipelago of the same name in the Philippines, situated on the northwest coast of the island of Sulu, 580 miles almost due south of Manila, and 99 miles southwest of Zamboanga, Mindanao (Map: Philippine Islands, F 13). The old town, destroyed during the Spanish occupation of 1876-78, was the residence of the sultans from the time of the traditional first leader, Xarib, or Charib, who is reported to have come from Mecca during the latter part of the seventeenth century. The new town, laid out on the hill by the Spaniards at the time of their permanent occupation, is well constructed and fortified. The harbor is provided with a long stone pier and a lighthouse, and the town is an important shipping place. Since the protocol of 1877 between England and the German Empire and Spain, it has been a free port. The population is but a few thousand.

SULU (Sp. JOLÓ) **ISLANDS,** or **SOOLOO ISLANDS.** The southernmost group of the Philippine Islands. It extends between the Sulu and Celebes Seas from the western extremity of Mindanao southwestward to the northeastern extremity of Borneo (Map: Philippine Islands, F 13). Its combined area, excluding the Basilan group, which properly belongs to Mindanao and forms a separate province, is estimated at 1029 square miles. The archipelago is arranged in two main parallel chains, and consists of several minor groups, each centred around a large island. Of the latter the two largest are Sulu Island in the north and Tawi-Tawi in the south, whose areas, respectively, are 380 and 187 square miles. The number of islands counted is 188. The larger islands are of volcanic formation, and consist of mountains from 1000 to 3000 feet high, with several extinct volcanoes. The mountains are generally surrounded by a coast zone of coral deposits, and most of the smaller islands are wholly of coral formation and very low, though all are built on the summits of a subterranean mountain range. The climate, being more tempered by the sea, is cooler and more equable than that of Mindanao. The soil, a mixture of volcanic and coral detritus, is extremely fertile, and the vegetation is luxuriant. The flora is more distinctly related to that of the Philippines, especially Mindanao, than to the Borneo flora; the forests produce teak and other valuable timbers, and cocoanut and nipa palms are abundant.

Considerable areas in Sulu Island are cleared and cultivated, the chief crop being rice, while coffee, cacao, corn, hemp, cotton, and indigo are also raised. The industries include weaving for domestic use, the manufacture of cordage and of knives and hatchets, and pearl and shell fishing, the last being probably the most important. Trade is almost wholly in the hands of Chinese merchants, and consists chiefly in the exportation of pearl shell to Singapore and Manila and the importation of manufactured goods. The dominant race among the inhabitants are the Moros, a tribe of Mohammedan Malays, who had invaded and conquered the islands before the arrival of the Europeans. They practice polygamy and a mild form of slavery, which the United States Government has agreed not to abolish, though it has insisted that hereafter no person shall be enslaved. The people are governed directly by local chieftains called datos, who are more or less nominally subject to the Sultan of Sulu. The latter was confirmed in his title and authority by the United States Government. The population of the archipelago is estimated at 22,630. The capital is Sulu (q.v.).

When the Sulu Archipelago was visited by Magellan in 1521 it was already occupied by the Moros, and formed, together with its possessions in North Borneo, an independent State. The Moros showed a warlike and independent spirit, and remained almost up to the present time among the most formidable pirates in the Malay Archipelago. Spain claimed sovereignty over the islands and their dependencies, but did not exercise it beyond sending occasional punitive expeditions against the pirates, and her sovereignty was disputed by England and Germany. By 1875, however, Spain had gradually gained a foothold and begun to assume actual control. In 1877 traffic was declared free in the archipelago, and Spain abandoned her claim to North Borneo in favor of England. Finally in 1885 England and Germany formally recognized Spanish sovereignty in the islands. It had already been acknowledged by the Sultan in 1878. With the Philippine Islands the Sulu Archipelago passed into the possession of the United States in 1898. In December, 1899, a treaty was definitely concluded between the Sultan and the United States by which American sovereignty over the islands was recognized. The rights and dignities of the Sultan were acknowledged and an annual stipend was conferred upon him. The Moros were guaranteed immunity in the practice of their religion. Toward the end of 1903 hostilities broke out between the Moro chiefs and the United States forces. The latter, under the command of General Leonard Wood, inflicted a severe defeat on the enemy in the last days of November.

SULZER, zụl'tsĕr, JOHANN GEORG (1720-79). A Swiss æsthetic philosopher, born at Winterthur. Educated in Zurich, he went in 1742 to Berlin, where he entertained friendly relations with Euler and Maupertuis, became professor of mathematics at the Joachimsthaler Gymnasium (1747), then at the Ritterakademie (1763), and was elected a member of the Academy. His principal work, in which he sought to reconcile the doctrines of Wolf with the tenets of the French and English philosophers, is the *Allgemeine Theorie der schönen Künste* (1771-74; new ed., with literary additions by Blankenburg, 1792-94), supplemented by *Nachträge, oder Charakteristik der vornehmsten Dichter aller Nationen*, ed. by Dyk and Schatz (1792-1808). With Ramler he edited *Kritische Nachrichten aus dem Reiche der Gelehrsamkeit* (1750). Consult his autobiography (Berlin, 1809).

SUMACH (OF. *sumac, sumach*, Fr. *sumac, sommac*, sumach, from Ar. *summāq*, sumach, from *samaqa*, to come of good stock), *Rhus*. A genus of about 100 species of shrubs and small trees of the natural order Anacardiaceæ, distributed over almost all the world, except its coldest regions. The following species are of commercial importance: Venetian sumach (*Rhus Cotinus*), known also as wig sumach or wig tree, is a native of Southern Europe and Western Asia, and is often planted under the name smoke tree as an ornamental shrub. It has simple leaves and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The wood, which dyes yellow, and, with the addition of other substances, green and brown, is known in trade as young fustic. The leaves are astringent, and are used for dyeing Turkey red. The root is also used in dyeing, and the whole plant is used for tanning in Italy. The seed resembles the almond in flavor. The very acid fruit of the elm-leaved sumach (*Rhus Coriaria*), a native of the Mediterranean region, has been used from the earliest times as a condiment. Similar to this is the Virginian sumach, or stag-horn sumach (*Rhus typhina*), a native of almost all parts of North America, with curiously crooked

STAGHORN SUMACH (*Rhus typhina*).

branches, covered, when young, with a soft velvety down. The smooth-leaved sumach (*Rhus glabra*), a similar species, also North American, has acid leaves, which are used for domestic purposes. The collection of the leaves of the sumach, especially *Rhus typhina*, for tanning is an industry in parts of the South. The varnish sumach or Japan varnish tree (*Rhus vernicifera*), a native of Japan and Nepal, yields a varnish much used in Japan for lacquer-work. The expressed oil of the seeds becomes as hard as tallow, and is used for candles. In Australia

the wood of *Rhus rhodanthema* (or *Rhodasphæra rhodanthema*) is considered one of the most valuable cabinet woods. It is dark yellow with a satiny lustre, and takes an excellent polish. The leaves and bark are used in tanning. The name tanner's sumach is given to *Coriaria myrtifolia*, a European shrub of the natural order Coriariaceæ. The leaves are astringent, and are used for tanning and for dyeing black.

The popularly reputed poisonous American species are botanically confused. *Rhus Toxicodendron*, a low shrub, is believed to be common only at the South; *Rhus radicans*, the so-called poison oak or ivy, a low, trailing or climbing species, referred by some botanists to Toxicodendron, is more widely distributed. *Rhus vernix* (or *Rhus venenata*), the so-called poison alder, sumach, dogwood, or swamp sumach, has long been reputed to cause irritation of the skin in some people and to be inert in others, a reputation also pertaining to the preceding species. A saturated alcoholic solution of lead acetate is considered a specific.

SUMAROKOFF, sōō'mȧ-rō'kôf, Alexander Petrovitch (1718-77). A Russian poet. He was born in Finland, was well educated, entered the military service, became Count Rumyantseff's adjutant, and later reached a high rank. When the first permanent theatre was established at Saint Petersburg in 1756, he was made director, and also wrote plays for production at the theatre. Petty of character, quarrelsome, and overambitious, he left the capital, incensed at the insufficient recognition he had received, and began to stage his works at Moscow. After a time he got into disputes with the management of the theatre there, and in despair took to drink, dying in obscurity. Although clumsy and ineffective, his tragedies played an important part in the history of Russian morals. His comedies and satires have a great deal of genuine humor and wit. His works were published at Moscow (2d ed., 10 vols., 1787).

SUMATRA, sōō-mȧ'trȧ. One of the Sunda Islands, the most western, also the largest, not reckoning Borneo, of the Dutch East India Islands, separated from the Malay Peninsula by the Malacca Strait, and from Java by the Sunda Strait (Map: East India Islands, B 5). It extends in a northwest and southeast direction. Its length is 1050 miles; its breadth ranges from 90 to 240 miles. Area, 161,612 square miles.

The Bukit-Barisan mountain range, of primitive formation with a covering of eruptive rocks, lines the island along the whole western shore, and in the south and in the north diverges toward the east coast. The whole northern part of the island is in fact mountainous. The descent to the generally rocky shores on the west is comparatively short and results in numerous valleys and ports of safety. To the east, in all the central part, extend lower stretches of level and undulating country sloping eastward, where all the main rivers are found, flowing eastward, often through marshy flats at the coast. The greatest elevations in the island are in the north, the loftiest peak being 12,100 feet. Here in the vicinity of Lake Toba—the most important lake—are steppes averaging 4000 feet in elevation, and thinly wooded, but the contiguous lower plains are rich in forests and characterized by dry rice-fields. In the region next south are encountered volcanoes and deep river valleys. Further south, in the large middle belt of the island, are also volcanoes on the west, rising to about 10,000 feet. Here are Lake Maninju, covering nearly 50 square miles and occupying the sunken cone of a volcano, and Lake Singkara, of equal area. Out of the latter issues the Ombilin River, coursing over a high plain of Eocene formation, and rich in coal fields. This whole fertile region in the western part is thickly populated and forms the Padang section, at present the most valuable industrial and commercial part of Sumatra. The large, more or less alluvial, and plentifully watered southern part of the island is little known. Sumatra has eight active volcanoes. The western coast with its rich soil, timber, and mines has been much more favorable to development than the eastern. The main rivers are the Musi, Jambi, Indragiri, and Kampar. They are of little importance for navigation. Around a large part of the coast extend rows and groups of islands of more or less significance and once a portion of the mainland—Banka, Linga, Rupert, Simalu, Siberut, etc. As a whole, Sumatra geologically belongs to the neighboring continental regions; sandstone, limestone, and slate formations abound.

The equator passes nearly through the centre of the island; accordingly the even temperature is constantly high, the mean annual temperature ranging from 77° to 81° F. The annual rainfall varies from approximately 90 to 185 inches. The lower sections of the island are unhealthful, the higher are pleasant and habitable. Thunderstorms and waterspouts occur frequently, and earthquakes now and then. The flora is practically that of the Malay Peninsula and Borneo, containing a few remarkable special features, such as gigantic forms of arum. A large part of the island is overgrown with trees and foliage. The mountains are rich in tall timber. Oak, camphor, and teak trees abound. Sumatra is unsurpassed for fauna, nearly all the large equatorial types being present. Buffaloes are the leading live stock. The rhinoceros, elephant, tiger, tapir, panther, deer, and many species of the ape are also largely represented. The supply of minerals is large. The island yields coal abundantly, and large tin deposits on Singkap Island on the east coast are being worked. Petroleum wells flow in the Palembang region, and there is an important output of petroleum in Langkat.

Agriculture is the occupation of the natives. All the tropical crops are or can be grown. The native princes and the Government farm out land to cultivators. The natives skillfully manufacture filigree articles in gold and silver, fabrics, and household articles. The northeast coast, around Dili, is a rich and extensive tobacco country, which produced in 1899 about 53,000,000 pounds of tobacco. The pepper trade is important. Coffee, bamboo, rubber, copra, and gums are also exported.

Sumatra is called one of the outposts of the Dutch East Indies. Its government appears to be in a somewhat transitory state, but is patterned after that of Java. The Dutch control in the interior is as yet but nominal. The various portions are known as the West Coast, the East Coast, Benkulen, Lampongs, Palembang, and

Achin, the first containing one-half the people of the island. Sumatra has a Governor (under the Governor-General of the East Indies), a President, Comptroller, etc. The 8 administrative districts are called residences. The Residency of Rhio includes several hundred islands off the east coast. A Government railway extends from Padang to the great coal mines in the adjacent interior. There is a railway from Medan to the coast, and one will operate from Achin along the northern coast. In 1900 Sumatra had 200 miles of railway. There are many good roads in various coast districts, and there is now a fair roadway from Palembang to Benkulen. Padang, Achin, Dili, Benkulen, and Palembang are the leading towns.

The population of Sumatra exceeds 3,000,000. The Europeans number about 6000, and the Chinese about 100,000. The natives of Sumatra, exclusive of the intruding Hindus, Arabs, Tamils, Indo-Chinese, and Chinese, belong to the Malayan stock, linguistically and physically, although some authorities group as 'Indonesians' such peoples as the Battaks and a few others. Among the most important and most interesting tribes are the Achinese of the extreme northwest, noted for their long struggle against the Dutch, the Battaks of the northern interior and northwest coast, and their neighbors in the Nias and Batu Islands, the Kubus, a very primitive people of the forests and marshy regions of Palembang, the so-called Menangkabau Malays of the middle of the island and other parts east and west, the Palembangs, Redjargs, Passumahs, Lampongs, and other tribes to the south, and the Abongs. The Malayan people of Sumatra exhibit many varieties of culture, from that of the forest-dwelling Kubus and other tribes of a primitive sort to those who under Hindu, and centuries later under Mohammedan influences, reached a considerable degree of culture, with religious and commercial as well as political development and expansion. The first intrusions of Hindu life and culture into Sumatra began some time before the Christian Era. Traces of Hinduism are evident in architecture, religion, and language. It was in all probability from Java that Buddhism in the sixth century made its way into Sumatra, where, however, it never obtained general vogue. The Battaks, some of whose divinities bear corrupted Indian names, possess an alphabet of Hindu origin. Hindu influences were probably at their height in the eighth century. From the thirteenth to the fifteenth century Mohammedan influences prevailed and many of the tribes were converted to Islam, and a number of sultanates were established. The Mohammedan influence upon politics, religion, and language was great. Since then the various European conquerors and intruders (Portuguese, English, Dutch) have made themselves felt, but chiefly in the coast regions. A considerable portion of the interior is still only nominally subject to the rule of the Dutch. On the whole the native population of Sumatra, as is also the case in Java, is on the increase. Mohammedanism is generally professed in the coast districts and also to a great extent in the interior.

Marco Polo visited Sumatra in 1292, and the first Portuguese in 1508. In the seventeenth century the Dutch obtained a firm foothold, having forced out the Portuguese. From 1812 to 1819 the English held the island. In 1825 Benkulen, where the English had been established for nearly a century and a half, was transferred to the Dutch. The conquest of the natives has been in progress since the discovery of the island, and has not yet been entirely completed. The Sultan of Achin, in the northwest, with whom a war has been going on since 1873, has especially proved troublesome.

SUMBA, sōōm'bȧ, or SANDALWOOD ISLAND. One of the Sunda Islands (q.v.).

SUMBAWA, sụm-bī'wȧ. An island of the Dutch East Indies, one of the Sunda group, situated between Java and Flores. It is separated by Atlas Strait from Lombok on the west and by Sapi Strait from Komodo and Flores on the east (Map: East India Islands, E 6). Its area is given as 4300 square miles by some authorities, and as high as 5400 by others. Four mountain ranges traverse Sumbawa from west to east, the northern being volcanic, the southern containing a limestone formation. Mid-Sumbawa is a region of circular hills of lava and tufa, and the land is covered with a long silver-colored grass. The natives engage in agriculture. Sumbawa, with its four free States, is included, for the administrative purposes of the Dutch, under Residency No. XI. of Insulinde or Island India. The population is put as low as 75,000 and as high as 150,000, nearly all Mohammedan Malays. There are about 12,000 foreigners, who control the trade.

SUMERIAN LANGUAGE. The language supposed to have been spoken by the non-Semitic inhabitants of the Euphrates valley who were gradually absorbed by the invading Babylonians. This language, according to the view of a majority of Assyriologists, has been preserved in a number of inscriptions. The first successful decipherers of the cuneiform characters, Hincks, Rawlinson, and Oppert, observed that the wedge-shaped signs were employed in writing languages not akin to the Assyrian, that the inventors of this system of writing cannot have been Semites, since the signs have syllabic values and some characteristic Semitic sounds are not represented, and that one of these languages was used in Babylonia itself. Hincks thought that these languages were Aryan; Rawlinson regarded them as Scythian, meaning by this term Mongolian; Oppert considered the Babylonian non-Semitic tongue as Kasdo-Scythian. The term 'Accadian' was first used by Rawlinson in 1855, the term 'Sumerian' by Oppert in 1869. There was practical unanimity among all Assyriologists before 1874 as to the agglutinating and non-Semitic character of this language. In that year, however, Halévy began his protest against the very

assumption that the Sumerian language ever existed. He first attempted to prove that the Sumerian language did not belong to the Turanian family and that the Turanian people cannot be supposed to have lived in Babylonia, and then maintained that the texts claimed to be Sumerian could be regarded as composed in an ideographic writing invented by the Assyrians in addition to the phonetic system and having the same values in pronunciation. Of the Sumerian signs in the syllabary, he found Semitic values for 114. In 1876 Halévy modified his view by admitting that the Sumerian signs could not have been pronounced like the ordinary Assyrian words. In his opinion, the so-called Sumerian was only a hieratic or priestly system of writing used as a cryptography for purposes of concealment. It was made from the other not only by the peculiar choice of ideograms, but by the apocopation of the closing vowel or syllable, changes of vowels and consonants, transpositions of syllables, and transfers of rarer meanings to common forms. Consequently it was to be regarded not only as a priestly system of writing, but as an artificial language constructed for certain occult purposes. Against this theory especially Oppert and Lenormant, Sayce, and Schrader urged many arguments, such as the impossibility of finding real Semitic values for the Sumerian signs and the improbability of an artificial language having been created as a secret means of communication between priests and then used for inscriptions in which kings recount their victories and their building enterprises. In 1880 Haupt indicated the existence of two dialects, *Emeku* and *Emesal*, of the Sumerian as shown by certain differences observed by earlier scholars without full appreciation of their significance. Even in view of this fact, explained by Halévy as due to varieties of cryptography, the difficulty of classifying the Sumerian, the apparent silence of the monuments concerning a nation speaking this language and conquered by the Babylonians, and the manifest influence of the Semitic speech on the vocabulary, led some scholars to hesitate. Meanwhile the study of the Sumerian, on the assumption that it was a real language, continued. Lehmann's investigations rendered it probable that the native name of the people speaking this language was *Shumeri* and that their home was in South Babylonia, in distinction from the *Akkadi*, who were the Semites and had their centre in North Babylonia.

The Sumerian is found in bilingual syllabaries and word-lists, bilingual hymns and prayers, bilingual inscriptions of kings, and many unilingual inscriptions. Of these the earliest show the least evidence of a Semitic influence. These are in the *Emeku* dialect. Those in the *Emesal* dialect naturally reveal more traces of the Semitic vernacular. Even within the *Emeku* dialectical differences have been observed, and the *Ememalah* may represent a dialect spoken in Miluhha. (See MINÆANS.) Sumerian loan-words in the Assyrian—of which Leander has counted 217—are taken from the *Emeku* dialect. The Sumerian is made up of monosyllabic roots and shows a tendency to triliterality; it is fond of compounds, which are rarely found in the Semitic languages, and expands its nouns by many prefixes and suffixes; it has no gender. The plural is often formed by duplication, as *kur-kur*, 'lands,' and sometimes by *ini;* the genitive is sometimes expressed by the suffix *ge* or *gid;* instead of prepositions it has post-positions, such as *-shu*, 'to,' *-ta*, 'from,' *-da*, 'with;' the pronouns are either independent or pronominal suffixes, but altogether different from the Semitic; the numerals resemble the Semitic only in making the twenties, thirties, etc., in the plural while the forms are entirely different; the verb has practically the same derived stems as the Semitic and Hamitic, but has a greater variety of prefixes, infixes, and suffixes. The attempts to discover the affinities of this language have not yet been successful, but it is probably the oldest known language in the world. From the Sumerian vocabulary it is evident that the people who spoke this language had reached a comparatively high civilization. The sexagesimal system was in vogue, and the beginnings of astronomy and mathematics are with much plausibility ascribed to the race who spoke the *lishan Shumiri* or Sumerian language.

SUMIDA-GAWA, sōō'mē-dä-gä'wä. A river in the island of Hondo, Japan, rising northwest of Tokio on the border of the provinces of Musashi and Kai, and entering the Bay of Tokio, after a course of some 90 miles. It is navigable for small boats. In Tokio it is a place of popular resort. On its banks are tea-houses, temples, and the great avenue of cherry trees at Mukojima. It is crossed by numerous bridges. In July it is the scene of a great festival called 'river opening,' when the tea-houses are illuminated, a great display of fireworks is given, and the river is covered with gayly decorated boats filled with pleasure parties.

SUMMARY PROCEEDINGS (from Lat. *summa*, main thing, substance, sum, fem. sg. of *summus*, superlative assigned to *super*, above, over). Proceedings in the nature of trials which are conducted before judicial officers without juries, and in a speedy and peremptory manner. Such proceedings must be specially authorized by statute, as they are not sanctioned by the common law. The Federal Constitutional guaranty of the right to trial by jury does not extend to such civil and criminal cases as were not triable by jury at common law, thus leaving the States free to dispose of such cases by summary proceedings

if they deem it expedient to do so. Most of the State constitutions also secure the right to trial by jury in all important cases. However, for the speedy administration of justice in trivial cases, both civil and criminal, the statutes of nearly all the States provide for the determination by summary proceedings of such petty misdemeanors as the violation of municipal ordinances as to fast driving, etc., disorderly conduct, and other minor offenses.

Certain proceedings for the ejectment of tenants are also known as summary proceedings in some States. See JURY; TRIAL.

SUMMER. A principal horizontal beam. The term, which is found in old English architecture, applies to a chief beam of a floor, or what is ordinarily termed a girder. When a summer is used to support a wall or other superstructure, as in the front of a building, it is known as a breast summer (q.v.). Summer is also used to denote a stone at the top of a pier or of a wall where an arch, lintel, or other work is supported.

SUMMER DUCK. The wood duck (q.v.).

SUMMER REDBIRD, or TANAGER. See TANAGER.

SUM'MERS, THOMAS OSMUND (1812-82). A clerical author of the Southern Methodist Church. He was born at Corfe Castle, Isle of Purbeck, Dorsetshire, came to America in 1830, and joined the Baltimore Conference (1835). He was missionary to the Republic of Texas (1840), and was one of the nine preachers who formed the Texas Conference. He was transferred to the Alabama Conference (1843); was secretary of the Louisville convention where the Methodist Episcopal Church South was organized; subsequently he was secretary of every General Conference of his Church until his death. He was assistant editor of the *Southern Christian Advocate* (Charleston, 1846), removing to Nashville (1855); was elected general book editor (1845), serving until his death, and editing nearly all of the publications of the denomination. He founded the *Sunday School Visitor* and edited it for four years; he edited the *Quarterly Review* nine years. He was professor of systematic theology in Vanderbilt University and dean of the theological faculty (1872-82); and was chairman of the committee which prepared a revised edition of the hymn-book of his Church. He wrote numerous works, including a commentary in six volumes on the Gospels, Acts, and Romans (1868-74); *Baptism, a Treatise* (1853); *Biographical Sketches of Eminent Ministers* (1858); *Sunday Service of the M. E. Church South* (1867); *Systematic Theology*, edited by Tigert (1888). For his life, consult Fitzgerald (Nashville, 1884).

SUMMER SCHOOL. The name applied either to institutions the sole purpose of which is the giving of instruction during the summer months, or to the summer sessions of any institutions of learning. Some universities in the United States frequently select from their regular programmes such subjects as will be suitable, and offer courses during the summer months. The successful completion of summer school courses gives credit toward the degrees of the institution at which they are taken. Other summer schools exist independently, usually at some situation favorable for summer resort. Such are the schools at Chautauqua, N. Y., at Martha's Vineyard, etc. Conditions of admission are either not required or are not severe. Certificates are given for work done, and frequently such work is allowed to count toward college degrees.

SUM'MERSON, ESTHER. The heroine of Dickens's *Bleak House*, the natural daughter of Lady Dedlock and Captain Hawdon, and ward of Mr. Jarndyce. She marries Allan Woodcourt, a surgeon.

SUMMER YELLOWBIRD. See WARBLER.

SUMMIT. A city in Union County, N. J., 12 miles west of Newark; on the Morris and Essex division of the Delaware, Lackawanna and Western Railroad (Map: New Jersey, D 2). It is attractive because of its elevation and the beauty of its scenery and is largely inhabited by New York business men. It has a Fresh Air and Convalescent Home and the Arthur Home for Orphans. There is a silk factory with several hundred hands. Population, in 1890, 3502; in 1900, 5302.

SUMMONS (OF. *semonse*, Fr. *semonce*, summons, admonition, fem. sg. of p.p. of OF. *semoner*, *somoner*, *semondre*, Fr. *semondre*, to summon, from Lat. *submonere*, to remind secretly, from *sub*, under + *monere*, to warn). A writ or process by which a defendant is notified to appear in court and answer the cause of action alleged in the plaintiff's complaint or declaration. It has superseded the *original writs* for the purpose of beginning an action in England and most of the United States. In the absence of statutory provisions to the contrary, a summons must be signed by the clerk of the court in which the action is brought, but under the codes it is usually signed by the plaintiff's attorney. For method of service, see SERVICE OF PAPERS. See also PROCEDURE; WRIT.

SUMMUM BONUM. See ETHICS.

SUM'NER, CHARLES (1811-74). An American statesman. He was born in Boston, Jan. 6, 1811; graduated at Harvard in 1830; entered the Harvard Law School the following year, and was admitted to the bar in 1834. Throughout his early years he maintained an extraordinary literary activity, writing chiefly upon legal topics, and occasionally appearing on the platform. His strength becoming overtaxed from the labor of editing an American edition of *Vesey's Reports*, he sailed for Europe in 1837, where he traveled for three years, devoting much of his time to the study of languages, literature, and history. Returning to America in 1840, he began to take an active interest in the anti-slavery movement, and in 1845 he delivered a notable Fourth of July oration at Boston, on "The True Grandeur of Nations," which Cobden pronounced "the noblest contribution ever made by any modern writer to the cause of peace," but it gave offense to the leaders of the Whig Party and led eventually to his withdrawal from that party. This oration was soon followed by others of great force, mainly on anti-slavery topics. He was a leader of the 'Conscience Whigs' of Massachusetts, who helped to form the Free-Soil Party. In 1851, through a combination of Free-Soilers and Democrats, he was elected to the United States Senate, of which body he was a member until his death. Here he waged a vigorous and uncompromising war on slavery. His first important speech was entitled "Freedom National, Slavery Sectional." This was followed

in 1856 by another on "The Crime Against Kansas," in which he reflected severely upon Senator Butler of South Carolina. This arraignment led to an assault in the Senate Chamber upon Sumner by Preston Brooks (q.v.), a Southern Representative and a relative of Butler, with the result that Sumner was so injured that he was incapacitated for Senatorial service for nearly four years. The attack led, indeed, to the disease to which Sumner finally succumbed. In December, 1859, he resumed his seat, but took little part in the debates until the middle of 1860, when he delivered a speech on "The Barbarism of Slavery." From the beginning he was recognized as one of the leading men in the Republican Party. In 1861 he became chairman of the Senate Committee on Foreign Relations, and made a number of able speeches on questions of foreign concern during the war, notably on the Trent Affair (q.v.).

He held the chairmanship of this important committee during ten years of a critical period. He took an active part in the debates on reconstruction measures and allied questions, ably advocating what came to be known as the 'suicide theory' of the status of the Southern States at the close of the war. (See RECONSTRUCTION.) He supported the impeachment proceedings against President Johnson and secured the enactment of a civil rights law to secure equality of treatment to negroes in hotels, theatres, etc., which was subsequently declared unconstitutional by the Supreme Court. He broke with the Grant administration, and in 1872 joined the Liberal Republican movement in advocating the election of Greeley for President. Sumner's *Works* were published in 15 volumes (Boston, 1874-83). Consult an elaborate *Memoir* by his friend E. L. Pierce (4 vols., Boston, 1877-93), and a short biography by Moorfield Story (Boston, 1900), in the "American Statesmen Series."

SUMNER, EDWIN VOSE (1797-1863). An American soldier, born in Boston, Mass. He was educated at Milton Academy, entered the United States Army, distinguished himself in the Black Hawk War, and was engaged in fighting Indians on the Western frontier. In 1838 he was placed in command of the school of cavalry practice at Carlisle Barracks, Pa. In the Mexican War, before the outbreak of which he had attained the rank of major, he participated in all the engagements of Scott's army in the advance from Vera Cruz to the City of Mexico, was wounded while leading a cavalry charge at Cerro Gordo, and for gallantry in holding in check a body of 5000 Mexican lancers at Molino del Rey was brevetted colonel. In 1857 he conducted a successful campaign against a hostile band of Cheyennes. In March, 1861, he was promoted to the rank of brigadier-general, and relieved Albert Sidney Johnston (q.v.) of the command of the Department of the Pacific. In the following year he was recalled and placed in command of the First Corps of the Army of the Potomac. He distinguished himself in the Peninsular campaign, particularly in the battle of Seven Pines (q.v.); was twice wounded in the Seven Days' Battles before Richmond; was brevetted major-general in the Regular Army and was appointed major-general of volunteers; and took part in the battle of Antietam, in which he was again wounded. He commanded the right wing of Burnside's army at Fredericksburg. Relieved at his own request after the appointment of Hooker to succeed Burnside, he was assigned to the command of the Department of Missouri, and died suddenly while on his way thither.

SUMNER, INCREASE (1746-99). An American jurist, born at Roxbury, Mass. He was educated at Harvard College, where he graduated in 1767, and studied law in the office of Samuel Adams. He was admitted to the bar in 1770, and he was a member of the State Constitutional Convention of 1779. In 1782 he was elected to Congress, but at the same time was offered an associate justiceship of the Supreme Court, which he held till 1797. In 1789 he was a member of the convention which adopted the Constitution of the United States. In 1797 he was elected Governor of Massachusetts, and held that office during the remainder of his life.

SUMNER, WILLIAM GRAHAM (1840—). An American political economist and educator, born at Paterson, N. J. He graduated at Yale in 1863, studied at Göttingen and Oxford, and was tutor at Yale in 1866-69. Ordained in the Protestant Episcopal Church in 1867, for some time he was assistant at Calvary Church, New York, and rector at Morristown, N. J. After 1872 he was professor of political and social science at Yale, where he attracted public notice by his pungent and incisive advocacy of free trade in lectures, essays, and books. Among his chief publications are: *History of American Currency* (1874); *Lectures on the History of Protection in the United States* (1875); *Life of Andrew Jackson* ("American Statesmen Series") (1882); *What Social Classes Owe Each Other* (1882); *Essays in Political and Social Sciences* (1883); *Protectionism* (1885); *Robert Morris* (1891); *The Financier and Finances of the American Revolution* (1892); and *A History of Banking in the United States* (1896).

SUMO, sōō'mō. A Central American linguistic stock. See ULUA.

SUMPTUARY LAWS (Lat. *sumptuarius*, relating to expenditure, from *sumptus*, expenditure, expense, from *sumere*, to take up, choose, apply, spend, from *sub*, under + *emere*, to take, buy). Laws to prevent extravagance in private expenditure, and indirectly to prevent immorality and crime. The purposes of sumptuary legislation may be grouped under the following heads: (1) To prevent poverty and diminish the cost of supporting the poor; (2) to increase the possible revenue of the State by diminishing private expenditure; (3) to prevent luxury when considered an evil; (4) to favor certain commercial or political interests; (5) to enforce class distinctions; (6) to prevent the consumption of commodities, as liquors and tobacco, which are considered dangerous to health and morals. Sumptuary laws were common in ancient legislation. By means of them Greece endeavored to inculcate simple habits of life among her people. Women, except prostitutes, were forbidden to wear expensive attire, as gold or embroidered apparel. The laws of Solon forbade costly banquets and funerals. At an early period in Roman history the censors, to whom was intrusted the superintendence of public and private morality, punished all persons guilty of luxuri-

ous living; but as the love of luxury grew with the increase of wealth and foreign conquest, various legislative enactments were passed with the object of restraining it. The Twelve Tables limited expenditures for funerals. Other early laws of Rome limited the expenditures of women, specified the number of guests who might be entertained at a single time, and fixed the amount which could be spent on entertainments. A later law made guests, as well as those who entertained, liable for a violation of these regulations.

Sumptuary laws found favor in England from the time of Edward III. down to the Reformation. In the reign of Edward III. one act prohibited more than two courses at a meal or more than two kinds of food at a course, except in the principal festivals of the year, when three courses were allowed. Another act prescribed the kinds of clothing the various classes might wear, except the orders of the nobility above the knights. Similar legislation prevailed in Scotland, France, Spain, and Italy.

When the mercantilistic theories of government emerged nations endeavored to control consumption by prohibiting the use of commodities produced abroad. It was held that the luxury of a people enriched other nations and impoverished their own. An English law prohibited the wearing of silk in order to encourage the manufacture of woolen goods in England. In France a law at one time prohibited the wearing of gold and silver embroidery, silks, and fine linens.

Aside from protectionism sumptuary legislation to-day comes under the head of the police regulations and is aimed to preserve the public health and morals. Under the United States Federal and State constitutions no restriction can be placed on the consumption of commodities or traffic in them, save as the public health, protection, and safety require it. The chief restrictive legislation is directed against the traffic in intoxicating drinks, and takes the form of high license requirements for the privilege of selling liquors, or in the prohibition of the right to deal in liquors altogether.

SUMTER. The county-seat of Sumter County, S. C., 43 miles east by south of Columbia, on several divisions of the Atlantic Coast Line Railroad and the Southern Railway (Map: South Carolina, D 3). It is known for its large trade in cotton. There are a cotton compress, cotton and cottonseed-oil mills, lumber mills, telephone factories, coffin and casket factories, and a manufactory of golf sticks. Population, in 1890, 3865; in 1900, 5673.

SUMTER, FORT. See FORT SUMTER.

SUM'TER, THOMAS (1734-1832). An American soldier, born in Virginia. He early removed to South Carolina; accompanied several expeditions against the Cherokee Indians; served under Braddock in 1755, and in March, 1776, became lieutenant-colonel of the Second Regiment of South Carolina Riflemen. Until the capture of Charleston (1780), he served in the interior of the State against the Loyalists and Indians; but subsequently raised a regiment in North Carolina and engaged actively in partisan warfare. On July 12, 1780, he defeated a force of mounted infantry under Captain Huck, and soon afterwards was made a brigadier-general of State troops. On August 1st he made a spirited but unsuccessful attack on Rocky Mount, and on August 6th defeated 500 regulars and Tories at Hanging Rock, but, his men dispersing, he was subsequently driven back. He then by a brilliant movement cut Cornwallis's line of communications between Charleston and Camden, capturing a supply train with its convoy; but three days later his force was almost annihilated by Tarleton at Fishing Creek. Enlisting another regiment, he defeated Major Wemys at Broad River (November 9th), and on November 20th repulsed an attack of Tarleton at Blackstock Hill, the latter losing 200 in killed and wounded, while the Americans lost 3 killed and 4 wounded. Here Sumter was severely wounded, but he returned to the army in February, 1781, and continued to render the most efficient service as a partisan commander. After the war Sumter sat in the State convention of South Carolina which ratified the Federal Constitution, was a member of Congress in 1789-93 and 1797-1801, and of the United States Senate from 1801 to 1809 and again from 1811 to 1817, and was United States Minister to Brazil in 1809-11. He was the last surviving general officer of the Revolution.

SUMY, sōō'mē. The capital of a district in the Government of Kharkov, Russia, situated 125 miles northwest of Kharkov (Map: Russia, D 4). The chief manufactures are machinery, tobacco, and liqueurs. Population, in 1898, 26,355.

SUN (AS. *sunne*, Goth., OHG. *sunnō*, *sunna*, Ger. *Sonne;* connected with AS. *sōwil*, Lat. *sol*, Gk. ἥλιος, *hēlios*, Ir. *sul*, Lith., Lett., OPruss. *saule*, Skt. *svar*, *sūra*, Av. *hvarə*, sun). The central governing body of the solar system (q.v.), and the chief source of our light and heat. To us the sun is the most important of all the heavenly bodies, since upon it depends the possibility of life upon the earth. The sun's apparent angular diameter is 32′ 4″; diameter in miles, 866,500; density, 1.41, water being 1; mean distance from the earth, 92,800,000 miles. The sun's distance from the earth is the fundamental unit of linear measures in cosmic astronomy. The method of the determination of this distance is given under PARALLAX.

Successive generations of astronomers have been able to gather much information as to the appearance, constitution, and structure of the sun. The theory at present accepted is as follows: The visible light-giving surface, as we see it in the telescope, is called the *photosphere*. We suppose it to be a collection of luminous clouds, holding in suspension certain particles condensed out of the extremely hot gaseous material of which the innermost nucleus of the sun is probably composed. Just outside the photosphere is a thin shell of gaseous matter called the *reversing layer*. This is doubtless composed of many substances such as we find among the known chemical elements of our earth. It is observed and its very existence is demonstrated by the spectroscope. According to Kirchhoff's theory, when light coming from incandescent solids or liquids is passed through vaporized matter, the vapors absorb or cut off the light from certain definite parts of the spectrum. To each vaporized substance belongs its own series of such points in the spectrum; and these correspond exactly to the positions which would be occupied by bright lines in a spectrum derived

directly from such vaporized substances themselves, if rendered incandescent. Thus the ordinary solar spectrum is crossed by certain well-known dark lines corresponding to the absorption of certain parts of the photospheric light by the absorptive effect of the reversing layer. Now if it were possible in some way to get rid of the light of the photosphere and examine directly the light of the reversing layer, we ought to see the spectrum of ordinary incandescent gases. This observation can actually be made at the time of a total solar eclipse. If we watch the solar spectrum very carefully just before the beginning of totality, when the moon's advancing edge is on the point of obscuring the sun completely, there will come a moment when nothing remains in sight but the outer or reversing layer. At that instant the dark lines in the spectrum are suddenly reversed, becoming bright like the lines in the spectrum of a gas heated to incandescence artificially in the laboratory. This remarkable observation was made by Young (q.v.) at the Spanish eclipse of 1870, and repeated photographically in 1896 by Shackleton, at the Nova Zembla eclipse.

The so-called *chromosphere* is a great layer composed of very hot gases, principally hydrogen, and surrounding the sun chiefly outside the reversing layer. It is supposed, however, that both these strata are mixed together, except that the hottest and densest gases are in the lower or reversing layer. This chromospheric layer can be seen for an instant at the beginning or end of a total solar eclipse, and it is found to consist principally of a mass of red flames. The color is due to the preponderating presence of hydrogen, and it is this color that gives rise to the name chromosphere or colorsphere. The presence of flame does not, however, indicate a process of combustion in the usual sense of the word. For instance, coal burning in an ordinary stove is really being combined chemically with the oxygen of the air, and chemical combination of that character is certainly not going on in the sun.

The most interesting features of the chromosphere are the *prominences*. These are great eruptive jets of red hydrogen flame bursting outward from the solar surface, sometimes to a distance of hundreds of thousands of miles into space. They were first seen during total solar eclipses, when the bright light of the central solar disk had been obscured by the interposed moon. Under ordinary circumstances the central solar light illuminates our terrestrial atmosphere very strongly, and enough of this light is reflected from the air itself into our telescopes to mask completely the fainter light of the prominences. But it has been found possible to study the prominences spectroscopically during full sunlight, and without waiting for a solar eclipse. This was first done visually in 1868 by Janssen, Lockyer (q.v.), and Huggins (q.v.), and photographically by Hale (q.v.) and Deslandres in 1890. The two latter astronomers working independently of each other, the former in Chicago and the latter in Paris, devised certain instruments called photographic spectro-heliographs, by means of which it is possible to take pictures of the chromosphere and prominences over the entire solar surface at once and in full sunlight. It has thus become known that the velocity of motion in these prominence eruptions may be as great as several hundred miles per second, indicating real explosions of incalculable force.

Extending far out beyond the chromosphere and prominences, and usually recognized as the sun's outermost envelope, is the *corona*. It is visible only at the time of total eclipse, when the central part of the solar disk is completely obscured. The appearance of the corona at such times is very sudden; the advancing edge of the moon slowly and gradually covers more and more of the sun's surface, until finally only a sickle-shaped filament remains. Then suddenly this too disappears, and on the instant the superb corona bursts into view, truly one of the most magnificent objects in the whole range of nature's phenomena. The inner corona, close to the solar disk, is very bright, even dazzling; farther out it fades by insensible gradations into a beautiful crown of filmy light. There are thread-like streamers, interlacing with complex involutions, and extending often many millions of miles into space above the solar surface.

Although observed visually from the most ancient times, it was not until the application of photography to astronomical observation that we have been able to fix with some approach to certainty the details of the coronal structure. See ASTRO-PHOTOGRAPHY.

Spectroscopically the corona reveals the presence of luminous gases, possibly containing in suspension particles of solid or liquid matter. No existing theory will explain quite satisfactorily its mechanical construction, so difficult is it to reconcile with gravitational law so enormous an extension outward from the sun. Possibly magnetic forces are wholly or partly responsible for its existence and equilibrium; certain it is that we still have in the corona one of the 'pending problems' of astronomy.

The chemical constitution of the sun has been studied with great care spectroscopically. The spectroscope, when suitably arranged for the purpose, enables us to compare solar light with light obtained in the laboratory from vapors of terrestrial substances raised to incandescence by artificial heating. In this way many terrestrial chemical elements have been identified in the sun; and we may consider extremely probable the hypothesis that sun and earth are composed of the same kinds of matter. This, if true, is a fact of great importance in its bearing on the origin and evolution of the solar system. (See NEBULÆ; COSMOGONY.) The most conspicuous phenomenon of the solar surface is the *sun-spots*. These are apparently great holes or depressions in the photospheric surface, usually having a dark spot in the middle, surrounded by a sort of radial grating. They vary in diameter from 500 to 60,000 miles for the central black parts, and range up to 150.000 miles for the surrounding less dusky portions. At times they are large enough to be seen with the naked eye. Their depth is very uncertain, and has been variously estimated from a few miles up to 2500. The *faculæ* are bright streaks seen in various parts of the photospheric surface, but usually near spots, and most conspicuous when approaching the edge of the solar disk. The spots usually begin as mere dots, and then grow gradually or rapidly to the enormous dimensions already stated. At times they break into several pieces, giving rise to a group or

collection of several spots. They are by no means immovable upon the solar surface, but have a motion of their own, those near the sun's equator traveling farther from the poles, and those in higher solar latitudes increasing their distance from the equator. But no sun-spots are ever found farther from the solar equator than latitude 45°, and few are nearer the equator than latitude 5°. One of the most remarkable things about the spots is the fact that their frequency is periodic. Once in about eleven years they have a maximum frequency, and astronomers are able to record their occurrence in greater numbers than usual. The cause of this periodicity is unknown.

Very interesting questions are raised by a study of the sun's light and heat. The quantity of light given by the sun, as compared with a standard candle, can be measured, and the sun's 'candle power' thus made known. Experiments show that this candle power is represented by the number 1575 with twenty-four zeros attached. The quantity of solar heat is no less stupendous; it has been estimated that the heat given out each hour by the sun is equivalent to the burning of a quantity of coal sufficient to cover the entire solar surface to a depth of more than twenty feet. The source of this vast amount of light and heat has been for a long time a mystery. It cannot be a question of combustion, because in that case the sun would have been consumed long ago, even if made of solid coal. The theory at present accepted is due to Helmholtz. It assumes that the sun's bulk is slowly contracting, and that the energy thus produced is turned into heat. It has been computed that a diminution of 150 feet annually in the sun's radius would be sufficient to account for the heat developed. Such a contraction would remain invisible even in our most powerful telescopes until it had continued for at least 10,000 years, and the process would need to continue for ten million years before the sun would lose the power to give us heat enough to keep life on the earth.

The rotation of the sun on its axis occupies about 25 days, 8 hours. This period is determined by watching the spots go around with the sun; and it is somewhat uncertain, because, as we have seen, the spots are not themselves quiescent on the solar surface. The rotation axis is inclined to the ecliptic plane, like that of the earth; if continued to the celestial sphere, it would pierce it midway between the bright star Lyræ and the Pole star. And there is one very peculiar feature in the rotation due perhaps to the fact that the sun's vast bulk has not yet been completely transformed from the gaseous to the liquid or solid stage. The equatorial regions rotate faster than those in higher latitudes, showing the existence of strong rotary surface currents of different velocities. No thoroughly satisfactory explanation of this phenomenon has yet been obtained by astronomers. See ECLIPSE; PLANETS; PERTURBATIONS; ORBIT; SOLAR SYSTEM. Consult: *Astrophysical Journal* (Chicago); Kayer, *Handbuch der Spectroscopie* (Leipzig, 1902); Young, *The Sun* (New York, 1900); Lockyer, *Solar Physics* (London, 1874); Proctor, *Sun* (London, 1871).

SUN, TEMPLE OF THE. An immense temple of ancient Rome erected by Aurelian, after the taking of Palmyra, on the site of the early Pulvinar Solis on the Quirinal Hill. It was built in imitation of the Eastern sanctuaries of the sun, and stood on a platform 92 feet high, from which the temple rose to a height of 110 feet. It was approached by two staircases, the steps of which now form the approach to the Church of the Aracœli, to which they were removed in 1348. The temple was of massive proportions. The 44 pillars of its peristyle were 65 feet high and 7⅔ feet in diameter, and a single fragment of the cornice, now in the Colonna gardens, weighs 100 tons. The vaults in the substructure were utilized for the storage of wines. The last portion of the temple, which formed part of the fortifications of the Colonnas, was destroyed about 1595, and the only remains of the building are three blocks in the Villa Colonna. The material was used in the Pope's palace on the Quirinal, Santa Maria Maggiore, and other buildings.

SUN AND LION, ORDER OF THE. A Persian civil and military order of merit with five classes, founded in 1808 by Shah Feth Ali on the model of the French Legion of Honor. The decoration is a silver star, bearing a lion with a sword. See Plate of ORDERS.

SUN ANIMALCULE. See HELIOZOA.

SUNBIRD. A bird of the tropical passerine family Nectarinidæ, which may be regarded as occupying nearly the same place in the Old World as do the humming-birds in America. They are all of small size, although none are so small as the smallest humming-birds, which they rival in brilliancy of plumage. Like them, they feed partly on the nectar of flowers, which they suck by their long bill, but chiefly on the minute insects which the flowers attract; they do not, however, flutter on the wing when feeding, like humming-birds, but perch on or beside the flower into which the bill is to be inserted. The species are very numerous, and are natives of the southern parts of Asia, the Eastern Archipelago, and Africa. The resplendent metallic plumage belongs only to the male, and only to the breeding season. They have been described and depicted in a magnificently illustrated monograph by Shelley, *The Nectariniidæ* (London, 1876-80). See Plate of CREEPERS.

SUN-BITTERN (so called because of its brilliant ocellated plumage). A curious bird of South and Central America, about the size of a chicken, allied to the cranes and more closely to the kagu (q.v.), the two species of which constitute the genus Eurypyga and the family Eurypygidæ. It haunts river banks, feeds upon small fish, crustaceans, and insects, and utters a soft or plaintive, long-drawn whistle. In the mating season it executes a fantastic dance, with its wings spread about its head, showing a pattern comparable to the sun's rays. Its nest is a rude affair in a bush or on a low tree branch. The best-known species is *Eurypyga helias*, which is beautifully variegated with brown, black, and white tints. This bird is often domesticated by the Brazilians. Consult Newton, *Dictionary of Birds* (New York, 1896). See Plate of BUSTARDS.

SUNBURY. The county-seat of Northumberland County, Pa., 54 miles north of Harrisburg, on the Susquehanna River, and on the Pennsylvania and the Philadelphia and Reading railroads (Map: Pennsylvania, E 3). There are the

Mary M. Packer Hospital, the court-house, jail, and parish house. Sunbury has silk and woolen mills, coffin works, planing mills, a foundry and machine shops, and flour mills. The government, under the charter of 1896, is vested in a burgess, chosen every three years, and a council. Sunbury was founded in 1772 on the site of an old Indian village and of Fort Augusta, built in 1756, during the French and Indian War. It was first incorporated in 1797. Population, in 1890, 5930; in 1900, 9810.

SUNDA (sŭn'dȧ) **ISLANDS.** A name commonly applied to all the islands of the Malay Archipelago lying west of the Molucca and Banda seas, and separating the China Sea from the Indian Ocean (Map: East India Islands, B 6). They include the four large Sundas, Sumatra, Java, Borneo, and Celebes, with their dependent islands, and the Lesser Sundas, Bali, Lombok, Sumbawa, Flores, Sandalwood Island, Timor, and others extending in a chain eastward from Java. The Sunda Islands are named from the Sundanese, ethnographically a Malayan people of the western part of Java. They are shorter in stature than the Javanese proper, and somewhat more brachycephalic. They have also been less influenced by Hindu culture.

SUN DANCE. The great annual religious ceremony common to all the tribes of the Plains with the exception of the Comanche and perhaps one or two others. In purpose it is a thanksgiving and invocation to the sun god and his representative the buffalo. Although anticipated as a yearly tribal event, it is usually 'made' or organized on each occasion in fulfillment of a vow by some particular individual in gratitude for recovery from sickness or for some other blessing. The management of details is in charge of certain priests, together with the warrior societies. The dance usually takes place about the beginning of summer and with all its attendant ceremonies lasts more than a week, the dance proper continuing four days and nights. The entire tribe assemble for the occasion and pitch their tipis in a great circle, in the centre of which is erected the medicine lodge of leafy cottonwood saplings. The centre pole of the lodge is decorated with streamers and symbolic paints, besides which a sacred bundle, usually wrapped in a buffalo skin, is fastened near the top. The centre pole is cut down by the women with much ceremony. The dancers are stripped and painted, the paint design differing in symbolic character at each stage of the dance, and are prohibited from eating or drinking during the four days of the dance. Among the Sioux, Cheyenne, and some other tribes they formerly also subjected themselves to voluntary torture by leaning their weight upon ropes fastened to wooden skewers driven through the flesh of their breasts and shoulders. Among the Mandan this torture was carried to an almost incredible degree; the victim was lifted completely from the ground and permitted to swing from the roof pole in this condition, after which one or more fingers were chopped off as a further sacrifice. Among the Kiowa such torture was unknown.

The dancers form a half circle about the centre pole, each one looking steadfastly upon the sacred bundle at the top and constantly facing the sun in its course, with their arms swinging at their sides, and holding between their teeth whistles of eagle bone with which they keep up a continual shrill whistling. At the west end of the medicine lodge is an altar of bushes and variously decorated twigs within which are the sacred buffalo skull, the sacred pipe, and other ceremonial objects. On another side are the drummers, who sing the songs of the sun dance to the accompaniment of a powerful drum. Throughout the ceremony there is a rapid succession of ceremonial performances, including addresses, feasting, giving of presents, initiation of new members into the various societies, and the piercing of the ears of the children born during the past year. At night there are games, story-telling, and more feasting, winding up with various social dances after the grand performance is at an end. The dance is still kept up among nearly all the Plains tribes, varying but little in details.

SUNDARBANS, or **SUNDERBUNDS,** sŏŏn'dĕr-bŭnz. A number of low islands, forming the delta of the Ganges, British India, and extending from the mouth of the Hugli to the island of Rabanabad (Map: India, E 4). Area, 7500 square miles. Only the northern part is inhabited, the southern being mainly jungle, infested by tigers, leopards, buffaloes, crocodiles, and snakes. The only town worthy of mention is Port Canning, connected with Calcutta by rail.

SUNDAY (AS. *sunnandæg*, OHG. *sunnuntag*, Ger. *Sonntag*, Sunday, from AS. *sunnan*, OHG. *sunnun*, gen. sg. of AS. *sunna*, OHG. *sunno*, Ger. *Sonne*, sun + AS. *dæg*, Ger. *Tag*, day). The first day of the week, observed by Christians almost universally as a holy day in honor of the resurrection of Christ. For some time after the foundation of the Christian Church, the converts from Judaism still observed the Jewish Sabbath to a greater or less extent, at first, it would seem, concurrently with the celebration of the first day; but before the end of the apostolic period, Sunday, known as 'the Lord's day,' had thoroughly established itself as the special day to be sanctified by rest from secular labor and by public worship. The hallowing of Sunday appears incontestably as a definite law of the Church by the beginning of the fourth century; and the Emperor Constantine confirmed the custom by a law of the State. Throughout the mediæval period the authority of the Church was so universally recognized that secular legislation in this regard was almost unnecessary. The Catholic Church then required, and still requires, abstinence from servile work on that day, and the assistance at mass of all who are not lawfully hindered. While the devout have attempted to make it in all respects a holy day, yet the mass of the people in Roman Catholic countries see no harm in spending a part of the day in social intercourse and amusements of various kinds. The tendency of Protestantism, however, has been to recur to the stricter Jewish observance, and to forbid any practice of the ordinary occupations of other days.

In the mediæval period the courts were presided over or dominated by the clergy, and Sunday early became in the legal sense a *dies non* (q.v.), on which legal proceedings could not be conducted. By the common law, however, all other business might lawfully be transacted on Sunday. The first substantial limitation of this right was imposed by the statute 5 and 6 Edw.

V., ch. 3, which provided that all secular labor should be unlawful on Sunday, except in cases of necessity. This was supplemented by the sweeping act of 29 Car. II., ch. 7, which prohibited all 'worldly business' on the 'Lord's day,' except where absolutely necessary, or for charity. These statutes have been substantially followed in practically all of the United States. The New England States were the first to regulate the observance of Sunday by a series of statutes. The Constitution of the United States prohibits the restriction of religious liberty or the enforcement of religious observances, and therefore, in law, Sunday is regarded merely as a civil day, which is a convenient one for the suspension of business, because of its observance as a holy day by a great majority of the people. These statutes are constitutional as a valid exercise of the police power. Works of necessity and great public convenience are usually excepted. Thus, a physician may carry on his practice, making lawful charges for his services; drug stores may keep open; transportation lines may handle freight and passenger traffic; milk dealers are usually permitted to deliver their product; and all persons whose business conduces to the public health are permitted to continue their activities. Where a cessation of operations would cause great financial loss, an exception is commonly made.

Where a person is traveling on Sunday in violation of law, and is injured, he is not precluded from recovering damages if he is otherwise entitled thereto. Although contracts entered into on Sunday were valid at common law, the courts of many States have interpreted their Sunday statutes as including this kind of a business transaction. A payment of a debt on Sunday is generally held to discharge the obligation. Wills executed on Sunday may be probated in most jurisdictions. In most States the legal Sunday begins at midnight on Saturday night, and continues twenty-four hours. In a few New England States Sunday ends at sunset. Many States exempt Hebrews and others who observe Saturday or some day other than Sunday as a holy day from the operation of the Sunday laws, but if such persons do not keep sacred any other day, they must suspend business on Sunday.

The need of one day in seven for rest from labor has long been recognized from an economic standpoint also. Not only has it been found that man produces more and better work by resting one day in seven, but also that he is a better physical and social being for observing such a rule. Sunday labor in the United States is, however, increasing. It has been estimated that in Massachusetts alone 50,000 persons work on Sunday. That the increase is general is shown by the growing opposition of the labor unions, and their frequent demands for shorter hours throughout the week, on the ground that they have no assurance of the Sunday respite.

SUNDAY-SCHOOLS. An agency of the Church for giving religious instruction to learners of all ages. The method of instruction is generally interlocutory and the subject of study more particularly the Bible. In its essentials the Sunday-school or Bible-school was an important part of the early Jewish educational system. About B.C. 80-70 Simon ben Shetach established a system of religious schools in connection with synagogues in Palestine, making attendance obligatory. Historians like Edersheim and Schürer confirm the general existence of such schools then and later in the time of Christ.

Bunsen says that "the Apostolic Church made the school the connecting link between herself and the world." Her catechetical instruction (cf. Luke i. 4; Acts xviii. 25) grew so steadily in acknowledged importance that church buildings were designed to provide special accommodations for the Bible-school. These early catechumenical schools included children and adults, who were taught individually, by the interlocutory method, subject matter beginning with the Old Testament story of creation and proceeding to practical Christian living. Gregory the Illuminator Christianized Armenia at the beginning of the fourth century by a compulsory system of Bible-schools for children in every city, while at that period similar schools were to be found in Mesopotamia, Cappadocia, Egypt, and elsewhere. In all these schools the Bible text was the main subject. In the Middle Ages the Bible-school idea was adhered to among the Waldenses, Albigenses, Lollards, Wiclifites, etc. A notable example of the Bible-school, apparently in many ways like our modern institution, were the schools of Charles Borromeo, Archbishop of Milan, in the middle of the sixteenth century. During the seventeenth and eighteenth centuries the direct study of the Bible gave way to the rote memorizing of set answers in catechisms not intended for such uses, and genuine Bible teaching was thus largely displaced.

It is to Robert Raikes (q.v.) that the modern revival of the Sunday-school is justly accredited, although numerous isolated Bible-schools were to be found both in England and America prior to his time and pioneer efforts were made in America independent of his example. (Consult Trumbull, *Yale Lectures on the Sunday-school*, Philadelphia, 1889.) According to contemporary testimony Raikes gathered some street boys in July, 1780, into a room in Sooty Alley, Gloucester, England, under the temporary care of a Mrs. Meredith, but soon transferred the school to the house and care of Mrs. Mary Critchley, in Southgate Street, where the first permanent Raikes school was established. The pupils were instructed not only in the Bible, but in reading, and in catechisms of the day. Later the school was held in Saint Mary de Crypt Church, then in the Crypt Grammar School, then at the Corn Exchange, and thence was transferred to the church again. The school seems to have had as many as 100 scholars at a time, the teachers receiving a shilling a day from Raikes for their work. Raikes worked quietly and experimentally for three years, and then on November 3, 1783, began to publish his idea in his newspaper, the *Gloucester Journal*. He published as early as 1785 *The Sunday Scholar's Companion*. In the extension of the Sunday-school idea Raikes accords much credit to John Nichols, of *The Gentlemen's Magazine*. The cause was notably furthered by Hannah More, John and Charles Wesley, and Whitefield, and even the Queen expressed an interest in the movement by sending for Raikes in order to hear his plan described. In 1784 Rowland Hill started a Sunday-school in London at Surrey Chapel. William Fox and Jonas Hanway were instrumental in organizing a gen-

eral Sunday-School Society in 1785, of which on June 11, 1787, Raikes was elected an honorary member. In 1786 five schools were reported in or near London. In ten years from that date the society had distributed 91,915 spelling books, 24,232 Testaments, and 5360 Bibles, to 1012 Sunday-schools and 65,000 scholars. From 1788 to 1800 the society had paid more than $17,000 to teachers. Gratuitous teachers were utilized in a school in Stockport, England, toward the close of the eighteenth century, and paid teachers gradually ceased to be generally employed. Before Raikes died, in 1811, there were 400,000 children in the Sunday-schools of Great Britain alone. In Scotland, where the need was not so greatly felt, and in New England, the Sunday-school met with little favor at first, as seeming to endanger the sacredness of the Sabbath, and to relieve the home of some of its duties. The Archbishop of Canterbury summoned a council of bishops to consider means by which the movement might be stopped. Yet notwithstanding all opposition the Sunday-school idea constantly gained in favor.

On December 19, 1790, twelve Christian workers held a meeting in Philadelphia, which led to the organizing on January 11, 1791, of a Society for the Institution and Support of First Day or Sunday Schools in the city of Philadelphia, with Bishop William White as president and Matthew Carey as secretary. The Reverend Robert May, of London, gave a new impetus to Sunday-schools in Philadelphia in 1811, urging the need of a general union. On January 13, 1816, in New York City, was formed the Female Union Society for the Promotion of Sabbath-Schools, and on February 26, 1816, the New York (male) Sunday-School Union. In 1817 the Sunday and Adult School Union was formed in Philadelphia with Alexander Henry as the first president, and this developed on May 24, 1824, into the American Sunday-School Union. The records of this great agency, interdenominational and national in its scope and support, showed in 1899, on its seventy-fifth anniversary, that through its efforts 100,928 Sunday-schools had been organized, with 578,680 teachers and 4,070,346 scholars, and that the union had distributed publications amounting in value to over $9,000,000.

At an anniversary of the American Sunday-School Union in Philadelphia on May 23, 1832, fifteen States were represented. It was then decided to call a general national Sunday-school convention to meet in New York in the autumn of that year to consider 78 questions on Sunday-school work sent out to 2500 persons throughout the country. The first national convention, therefore, assembled on October 3, 1832, in Chatham Street Chapel, New York City, and chose the Hon. Theodore Frelinghuysen as president. The National Convention as an independent organization met subsequently in Philadelphia, May 22, 1833; Philadelphia, February 22-24, 1859; in Newark, N. J., April 29-30, 1869; and in Indianapolis, April 16-19, 1872, at which convention the uniform lesson system was inaugurated, after much discussion, by the appointment of the first lesson committee to select the lessons from 1873 to 1879. The united interest of Bible-students in selected portions of the Bible, in the progress of the uniform lesson plan, has given rise to a literature, both permanent and periodical, that has widely popularized Bible study. The international lesson system now includes a special beginners' course of Bible study for the youngest children, and still other modifications are under discussion. Other lesson systems are in use in some schools and in a few denominations, but in the vast majority of schools the international uniform lesson system is used.

At the next convention in Baltimore, May 11-13, 1875, the convention became international in scope and name. This convention has met every three years since that time. It is composed of delegates from auxiliary State, Territorial, and provincial Sunday-school associations in North America. Its work is conducted during the triennium by an executive committee; a lesson committee, international and interdenominational in its personnel; a primary department; and a field workers' department. A World's Convention, under the auspices of the London Sunday-School Union and the International Executive Committee, was held in London, July 1-4, 1889, thus establishing an institution comprising all the countries of the world, and meeting since then in Saint Louis, Mo., September 3-5, 1893, and in London, July 11-15, 1898. In the improvement of teacher-training and Bible study what is known as the 'Chautauqua movement' has been an important factor. See CHAUTAUQUA.

The Sunday-school is the pioneer religious agency in new communities, and the conserver of neighborhood religious instruction for the entire family in every community where it exists. It is extended to frontier or sparsely settled districts in America by the various denominational mission boards, and by the American Sunday-School Union. It is stimulated to better work, and is made acquainted with the most recent methods, by means of conventions and institutes, some 18,000 of which are held in North America yearly, under the auspices of the International Convention and its auxiliary State, provincial, county, township, and district Sunday-school associations.

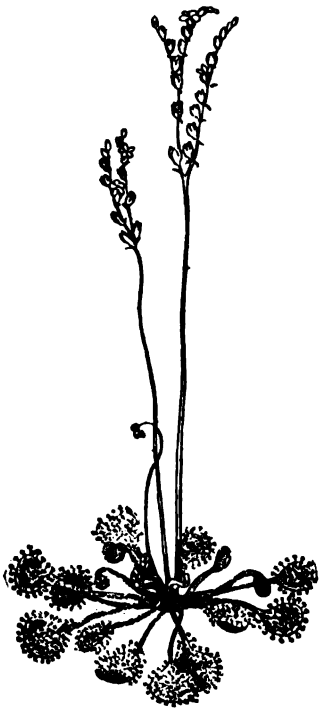
At the tenth international Sunday-school convention, held at Denver, Colo., in 1902, the following statistics were presented as to the Sunday-schools in the United States, including Hawaii and Porto Rico: Number of Sunday-schools, 139,817; officers and teachers, 1,419,807; scholars, 11,493,591; total enrollment, 13,092,703. In 1898 the corresponding figures for the entire world were: Sunday-schools, 254,698; teachers, 2,410,818; scholars, 23,227,330; total, 25,810,861.

BIBLIOGRAPHY. (1) Historical: Pray, *History of Sunday-schools and of Religious Education from the Earliest Times* (Boston, 1847); Watson, *The History of the Sunday School Union* (London, 1853); id., *The First Fifty Years of the Sunday School* (ib., 1873); *Centenary Memorial of the Establishment of Sunday Schools* (ib., 1881), a collection of informing addresses and papers containing valuable historical material; Trumbull, *Yale Lectures on the Sunday School* (Philadelphia, 1888), the most comprehensive and thorough treatment of the whole subject; Harris, *Robert Raikes, the Man and His Work* (Bristol, 1899); Brown, *Sunday School Movements in America* (New York, 1901), deals with special phases of Sunday-school progress, and the general field in America; Hamill, *A Brief History of the International Lessons* (Chicago, 1901). (2) Practical: Trumbull,

Teaching and Teachers (Philadelphia, 1884), the standard manual for the thorough study of the work of the teacher; Vincent, *The Modern Sunday School* (New York, 1887), a comprehensive detailed outlining of the school itself; id., *The Church School and Normal Guide* (ib., 1889), deals with the character of the institution and methods of Bible study and teacher-training; Schauffler, *Ways of Working* (New York, 1895), practical hints out of a varied experience; Foster, *A Manual of Sunday School Methods* (Philadelphia, 1899); Peters, *Practical Handbook on Sunday School Work* (Philadelphia, 1900); Oxtill, *The Organized Sunday School* (Nashville, 1901); Hamill, *The Sunday School Teacher* (Nashville, 1901); Pattison, *The Ministry of the Sunday School* (Philadelphia, 1902); Blackall, *Our Sunday School Work and How to Do It* (rev. ed., Philadelphia, 1902); Schauffler, *Pastoral Leadership of Sunday School Forces* (Nashville, 1903).

SUNDERBUNDS, sōōn'dĕr-bŭnz. A name applied to the islands forming the delta of the Ganges. See SUNDARBANS.

SUN'DERLAND. A seaport in the County of Durham, England, 14 miles northeast of Durham, at the mouth of the Wear (Map: England, E 2). It is one of the great coal-shipping ports of the world. Shipbuilding is an important industry. Machinery, glass, earthenware, ropes and chains, anchors, and other iron wares are extensively manufactured, and fishing is carried on to a considerable extent. In the vicinity are rich coal mines, of which the Pemberton, 2286 feet deep, is said to be the deepest in existence. On both sides of the river are extensive wet docks, much of the area of which has been reclaimed from the sea. The harbor, defended by batteries, is formed by two great piers, one 650 yards and the other 590 yards in length. Sunderland is a well-built town with broad streets. There are a fine town hall, an assembly hall, handsome club houses, a large infirmary, and a spacious workmen's hall. The public park contains 70 acres. The town came under the Municipal Corporations Act in 1835. The borough was extended in 1867 and again in 1895; it includes the townships of Bishopwearmouth, Monkwearmouth, and Monkwearmouth Shore. The Monkwearmouth portion of the town dates from a monastery of the seventh century, in which the Venerable Bede spent most of his life. Population, in 1891, 131,686; in 1901, 146,565.



SUNDERLAND, CHARLES SPENCER, third Earl of (1674-1722). An English statesman. He was the second son of the second Earl of Sunderland, and became Lord Spencer on the death of his elder brother in 1688. In 1700 he married Lady Anne Churchill, second daughter of the Earl of Marlborough. In 1702, on the death of his father, Spencer succeeded to the title. Through the influence of Marlborough, Sunderland obtained several important posts, and became a member of the famous Whig Junta, which for a time controlled the whole Government. In 1720 Sunderland brought about the establishment of the notorious South Sea Company (q.v.). When the crash came it was found that Sunderland had received a bribe of £50,000 from the company, and though he was acquitted by a party vote, he had to resign his offices. He retained, however, considerable influence until his death. Sunderland seems to have been a disagreeable and treacherous politician. He was a collector of rare books, and a patron of Addison and other men of letters.

SUNDERLAND, JABEZ THOMAS (1842—). A Unitarian minister, born at Howarth, in Yorkshire, England. He was educated at Madison (now Colgate) University, Hamilton, N. Y., University of Chicago, and Union Baptist Theological Seminary of Chicago. From 1886 to 1895 he edited the *Unitarian Monthly*. He visited India in 1895-96. He is author of *A Rational Faith* (1878); *What is the Bible?* (1878); *The Liberal Christian Ministry* (1889); *Home Travel in Bible Lands* (1894); *The Bible: Its Origin, Growth, and Character, and Place Among the Sacred Books of the World* (1893); *The Spark in the Clod: A Study in Evolution* (1902).

SUNDERLAND, ROBERT SPENCER, second Earl of (1640-1702). An English statesman. He was the only son of Henry Spencer, who was raised to the peerage in 1643. After some diplomatic service abroad he was made a member of Temple's reformed Privy Council of thirty members, and was one of the smaller inner Cabinet with which King Charles II. habitually conferred. Sunderland at first supported the Duke of York and then labored for the Exclusion Bill, which was to exclude the Duke from the succession. Thereby he lost the favor of Charles and his position in the Privy Council (1680). In 1682 he was restored to royal favor through the influence of the Duchess of Portland, mistress of Charles II., and the French Ambassador Barillon, and unscrupulously advocated the disgraceful French connection. He remained in office until the accession of James II., when his influence in the Ministry became greater than ever. Although there is reason to believe he gave some encouragement to Monmouth in his rebellion, he managed, with consummate art, to obtain the entire confidence of James, and in 1685 became Lord President and principal Secretary of State. In 1687 he privately conformed to the Roman Catholic Church, and afterwards openly professed his conversion. Yet we find him about this time in correspondence with the Prince of Orange, afterwards William III. With profligate but masterly dexterity he contrived to deceive both his master and Barillon, and to keep them in ignorance of the events that were passing in Holland. When the Prince arrived in England, Sunderland and his wife went to Amsterdam, whence he wrote to the new monarch, claiming his favor and protection on the ground that he had all along been in his interest. In 1691 he was allowed to return to England, and in 1697 was made Lord Chamberlain. Popular indignation, however, compelled him to resign within a few months. He spent the rest of his days at Althorpe, where he died September 28, 1702.

SUNDEW (so called from the dew-like drops exuded, especially in the sunlight), *Drosera*. A beautiful and interesting genus of about seventy-five species of plants of the natural order Droseraceæ, several species of which are natives of American bogs, etc. A common species is the round-leaved sundew (*Drosera rotundifolia*). Its leaves all spring from the root, and spread out in a rosette, from the centre of which springs the flower-stem or scape with a raceme of flowers

all on one side. The leaves of this and the other species are fringed and beset in all parts with hairs, which bear at their extremity viscid

SUNDEW (*Drosera rotundifolia*).

glands, which fold up when irritated, imprisoning insects and digesting them through the action of enzymes secreted by the plant. Consult Darwin, *Insectivorous Plants* (1875).

SUN-DIAL. See DIAL.

SUN-DOGS. See HALO.

SUNDSVALL, sŭns'vâl. A seaport in the Län of Wester Norrland, Sweden, 28 miles south by west of Hernösand, on the Gulf of Bothnia (Map: Sweden, G 5). It is known for its extensive lumber interests, and is engaged in shipbuilding and the manufacture of iron and steel. Population, in 1901, 15,087.

SUNFISH. The name of a variety of fishes; also given by sailors to jellyfish. (1) In the United States a group of numerous and familiar fishes of streams and ponds, related to the bass, and forming several genera of the family Centrarchidæ (q.v.). All are of small size, six to ten inches long, oval in shape, and much compressed. All are excellent eating. They are brightly colored, especially in the breeding season, and may be known by the black flap to the posterior edge of the gill-cover. Their feeding and breeding habits are similar to those of the fresh-water bass (q.v.). See Plate of DARTERS AND SUNFISH; and consult Jordan and Everman, *Fishes of North and Middle America* (Washington, 1900), and the authorities there cited.

(2) One of the strange oceanic fishes of the family Molidæ, related to the Diodontidæ; especially *Mola mola,* which seems to be composed of a huge head with small fins attached. (See Plate of ROCKFISH, SUNFISH, ETC.) They reach a weight of 300 to 1500 pounds, are scaleless, dull in color, clumsy, and often lie inert like a huge gray blanket on the surface of the sea sunning themselves and bending with the movements of the waves. The young are more fish-like, and were long considered entirely separate. They are of no use as food. There are about six species, one of which (*Ranzania truncata*) is called 'king of the mackerels.' Consult Dean, *Fishes Living and Fossil* (New York, 1895).

(3) The threadfish (q.v.) (*Alectis ciliaris*).

SUNFLOWER (probably so called from its yellow radiate disk), *Helianthus.* A genus of large herbs of the order Compositæ, containing numerous, mostly perennial species, all natives of America. The common sunflower (*Helianthus annuus*), an annual, one of the most important species, is a native of the tropics, where it sometimes attains a height of 20 feet and produces flower heads from 1 to 2 feet in diameter. In temperate climates it grows from 5 to 8 feet high. This species has become widely distributed throughout the United States as a weed, especially in the West and the Southwest. It was introduced into Europe about the middle of the sixteenth century. In Egypt, India, and Southern Europe, especially in Russia, the plant is grown for its seeds, which are eaten like nuts, and their oil, which is used for culinary purposes. The oil is also used in the manufacture of varnishes on account of its drying properties, which, however, are inferior to those of linseed oil. It is also used in soap-making and other manufactures. Sunflowers are cultivated somewhat in the United States and Canada for ornament, for forage, and for seed. On light, well-drained, well-tilled, and fertile soil a yield of from 30 to 50 bushels of seed per acre may be obtained. The preparation of the soil and its subsequent cultivation is similar to that for corn, but the distance between plants in the row should be from 12 to 16 inches. From 10 to 15 pounds of seed is required per acre. The heads are harvested shortly before they are thoroughly ripe to prevent loss of seed. Before storing they are carefully dried to prevent molding. The seeds are threshed out with flails.

AVERAGE COMPOSITION OF SUNFLOWER PRODUCTS.

	Water	Protein	Fat	Nitrogen-free extract	Crude fibre	Ash
	per cent.	*per cent.*	*per cent.*	*per cent.*	*per cent.*	*per cent.*
Whole plant	85.2	1.7	1.0	6.2	4.0	1.9
Heads	86.1	1.9	1.5	5.6	3.8	1.1
Seed	8.6	16.3	21.2	21.4	29.9	2.6
Sunflower seed cake	10.8	32.8	9.1	27.1	13.5	6.7

The whole plant and the seeds have been used to a limited extent as a feeding stuff, especially mixed with horse beans and corn fodder for making silage. The seed is frequently fed to poultry. The oil cake is fed especially in Northern Europe to fatten animals.

Sunflower stalks are useful as fuel when other materials are not abundant.

SUNG, sōōng. One of the seven great Chinese dynasties. It was founded in 960 by Chao Kw'ang-yin, a descendant of a family of officials of the T'ang dynasty (618-907), who had risen to high military command. With the Empire rent with disorder, and the hordes of the Liao Tatars threatening on the north, the army concluded to raise their general, Chao, to the throne. He at once proceeded to repel the Liao and unify the Empire by reducing the petty States. He introduced many reforms, and for sixteen years ruled with great wisdom and ability. The Liao, however, continued to encroach on Chinese territory, and in 1126, during the reign of the ninth Emperor, established their authority over all of North China, styling their dynasty the *Kin* or 'Golden.' The Sung fled south to Hang-chow (q.v.), which continued to be the capital of the diminished empire of the Southern Sung. Nine emperors ruled here until 1279, when Kublai Khan and his Mongols overthrew both the Kin and the Sung, and established the Yuen dynasty in 1280. Notwithstanding the harassments and encroachments of invading armies, the Sung period was one of great prosperity and advance in civilization and culture.

SUNGA'RIA, or DZUNGARIA. A name vaguely applied to a region of undefined extent in Central Asia (Map: Asia, H 4). It belongs to the Chinese Empire, and the name is generally restricted to the region lying north of the Tarim Basin in East Turkestan, between the Tian-Shan and Altai Mountains, and west of Mongolia. It is chiefly of historical significance, deriving its name from the Sungarians, a Mongolian people who attained their greatest power about the middle of the seventeenth century, when their kingdom embraced the territory between the Kuen-lun and the Altai Mountains, extending westward to Lake Balkhash. About 1670 the ruler of Sungaria entered into conflict with the Chinese, who completely overran the country. The Chinese were driven out in 1710 and for a short time the rulers of Sungaria were masters of Tibet. In 1759 the Chinese, after long campaigns, destroyed the reestablished Sungarian kingdom and made the country a part of their empire, peopling it in large measure with colonists from China.

SUNKEN BELL, THE (Ger. *Die versunkene Glocke*). A poetic play in blank verse by Gerhart Hauptmann (1896). It is a fairy-drama, the chief human character of which is Heinrich, a master bell-founder who has completed his crowning work, a bell which is to be hung in a church on a mountain inhabited by sprites. Through their hostility the wagon bearing the bell is overthrown and the latter is sunk in a mountain brook. Heinrich is injured and is nursed by the chief personage of the drama, Rautendelein, half child, half fairy, whose love changes Heinrich's standards and brings about the death of his wife.

SUNN. A plant (*Crotalaria juncea*) grown in India and some other warm climates for its fibre. See HEMP, SUNN; CROTALARIA, and illustrations on Plate of CRANBERRY, ETC.

SUN'NA (Ar. *sunnah*, custom, legal usage, tradition, from *sanna*, to establish a usage or law). In the original meaning among Moslems, the sayings and the example of Mohammed and his community, provided they are in accordance with the Koran, the meaning of which, however, is itself explained by the Sunna. As embracing traditional law, Sunna is divided into three parts: (1) what Mohammed did; (2) what he enjoined; and (3) what was done in his presence and not forbidden by him. The term is therefore (though incorrectly) used for the collections of moral and legal traditions known as *Hadith* (q.v.) traced to the Prophet, which supplement the Koran, somewhat like the Mishna (q.v.), which supplements the laws of the Pentateuch. The Sunna not only comprises religious doctrines and practice, but also civil and criminal laws, and the usages of common life, the way to eat and to drink, to dress, and the like. For the credibility and canonicity of a tradition, it was originally necessary that it should have been *heard* by one truthful witness; but this law was much relaxed in later times. By the beginning of the ninth century a large number of individual collections known as *Musnads* had been produced by different theologians, but the first who sifted them critically, and without regard to any special theological system, was Buchari (810-887). His collection contains 7275 single traditions, 4000 of which, however, occur twice in the work. Muslim, a younger contemporary (817-873), supplemented Buchari with another collection, containing 12,000 traditions, again including 4000 repetitions. Besides these, there are 'canonical' collections by Abu Daud (817-888), by Tirmidhi (830-914), a pupil of Buchari, and by Abu Maja (824-886), besides others that also enjoyed some measure of authority. The Sunna, as we have it in these collections, contains, broadly speaking, more truth than it is generally supposed to contain, and, critically used, is, besides the Koran, the most authentic source of a knowledge of Islam. A selection from the different collections (both canonical and otherwise), called *Mishkat Al Masabih*, has been translated into English by Matthews (Calcutta, 1809). The Arabic text of Buchari has been published by Krehl, *Le recueil des traditions musulmanes* (Leyden, 1862-68), and fragments of this work in German translation were embodied by Hammer-Purgstall in his *Fundgruben des Orients* (Vienna, 1810-19). Goldziher has a valuable treatise on the Hadith literature in his *Mohammedanische Studien*, vol. ii., pp. 1-274 (Halle, 1890).

SUNNITES, sŭn'īts (from Ar. *sunnah*, custom, legal usage, tradition, from *sanna*, to establish a usage or law). The orthodox sect in Islam; politically it may be described as the Centre, in contrast to extreme theories concerning the headship of the Church. The term arose in distinction to several tendencies which early asserted themselves, but especially differentiates that section which denies the claim of the Shiites (q.v.) for the peculiar authority of Ali, as the sole legitimate successor of Mohammed. (See MOHAMMEDAN SECTS.) These Shiites fast developed their peculiar theological and constitutional theories, and so drove their opponents to an understanding of their own position; as they were content with tradition and with things as they were, they called themselves Sunnites, or Traditionalists. The differences rapidly developed into those of a political and

ethnic character, the Shiites being found in the lands which were opposed to the Ommiads (q.v.), as Arabia, where independence was characteristic, and in Persia, which only by force of arms had submitted to Islam. But the decision between the two parties was by no means immediately reached. The fall of the Ommiads was brought about by Persian Shiite influences (750), although the new Abbasside dynasty which was installed soon threw in its lot with the Sunnites. In general the geographic centre of the Arab power, Mesopotamia and Syria, remained in the control of this party. But the Shiites maintained the contest. The latter as liberalists and theosophists possessed a strong following, especially among the cultured, and they often enjoyed immunity under free-thinking caliphs. The Empire was honeycombed with Shiite secret societies like the Assassins (q.v.), and Shiite dynasties arose in Egypt and at Bagdad. (See SHIITES.) But by 1100 Sunnism was master in Southwestern Asia. This party was able to maintain itself during the Mongol invasions, and with the favor of the Ottoman Turks it remains as the predominant body in Islam. At the present time orthodoxy outnumbers all its opponents by ten to one, and commands not only the whole Turkish Empire, but the millions of Moslems in Africa, India, China, Malaysia and the Philippines, non-Turkish Arabia, and Northern Africa (Morocco being practically Sunnite).

Within this conservative and orthodox body, apart from outer foes, there early developed all kinds of theological strife. Rationalistic and liberal parties developed, which opposed, one after another, the original principles of Islam, such as its views of God, and of heaven and hell, its doctrines of predestination and of the literal authority of the Koran. On the other hand, the crass views of the fanatical mob opposed anything like philosophy, even though orthodox. Traditionalism was not fitted to meet the dialectic methods of its opponents, who had learned from the ancient schools of culture, and was ignorant of the use of philosophy in self-defense. But the champion of orthodoxy arose in Al-Ashari (born 882). A member originally of the Mutazilite sect, which had gone to the extreme of rationalizing upon the faith and the Koran (see MOHAMMEDAN SECTS), he was led to the consciousness of this inconsistency, and openly abjured that heresy, henceforth devoting himself to the formulation of a scholastic philosophy in support of orthodoxy. This school encountered for long the opposition of the liberals and the ignorant, but about 1050 Ashari's triumph became evident. His philosophy was continued and popularized by Al-Gazali (q.v.), who established the pietistic principle of Sufism, which may be compared to the Christian emotional principle of faith. Since Ashari and Gazali no commanding theologian has arisen and no further philosophic advance has been made in Islam.

With reference to the head of Islam, Sunnism still as ever lacks a definite principle. Since 1658 the Ottoman Sultan has claimed the caliphate, although he possesses but fictions of the traditional requirements, and he holds his power by force and through the agreement of the faithful. Hence Sunnism is not bound to the dynasty at Constantinople, and many of its thoughtful minds would regard the fall of the Ottoman power in the light of redemption for the Church. Contrary, therefore, to the original theocratic constitution of Mohammed there has arisen a division between the spiritual and the political forces. Political power is wielded by the Sultan, but the spiritual rule is in the hands of the Ulema (q.v.) of Constantinople, a close corporation of lawyer-theologians. Its chief, the Sheik-ul-Islam, is appointed by the Sultan, but only out of that body, and he possesses large independent powers which the Sultan dare not invade. He is the chief spiritual person in orthodox Islam.

Within the Sunnite body exist four different schools of law, those respectively of the Hanbalites, the Hanifites, the Shafiites, and the Malikites (so named after their respective founders). The first code is confined to the Wahabites (see WAHABIS); the second to Upper Egypt and North Africa; the third prevails in Lower Egypt, Southern India, and Malaysia; the fourth is followed by the Turks and by the Moslems of Central and Northern Asia. These schools arose in the second and third centuries of the Hejira and represent so many different compositions between tradition and progressive law. They are at peace with one another now, and divide orthodox Islam among themselves, each people being allowed to live by its law, and each lawyer electing his choice. But in the Ottoman Empire there exists the contrast between this canon law and the secular law. The latter proceeds from the authority of the Sultan or is the ancient secular law of the land; the other, the law of the Church, is confined mostly to domestic matters, and it is one of the grievances of the orthodox that the legal authority of the Church is thus put into abeyance by the secular arm. Here again the analogy may be drawn with the dispute which has prevailed in European Christendom between the canon and the civil law. Therefore, both in its past history and in its present condition, Sunnism is by no means to be regarded as a homogeneous body or practice. For literature, see MOHAMMEDANISM; MOHAMMEDAN SECTS.

SUNNYSIDE. A gabled stone house on the Hudson River near Irvington, three miles south of Tarrytown, noted as the home of Washington Irving, and described in Irving's sketch entitled *Wolfert's Roost*, the former name of the mansion. The house, in which the author's study has been preserved in its original condition, is overgrown with ivy from Abbotsford.

SUNSTONE, or HELIOLITE. A variety of aventurine, oligoclase, or feldspar, which when polished yields internal yellowish or reddish reflections emanating from crystals or flakes of iron oxide that are contained in the mass. The finest specimens, which show a brilliant play of colors, are found in Norway, although gem varieties occur in the United States at Crown Point, N. Y., and Media, Pa.

SUNSTROKE. See HEAT-STROKE.

SUN-WORSHIP. See NATURE-WORSHIP.

SUO'VETAURIL'IA (Lat., sacrifice of a boar, a sheep, and a bull, from *sus*, boar + *ovis*, sheep + *taurus*, bull). A Roman sacrifice, which was offered to Mars, in the lustrum, or purification of the people, on the Campus Martius at the Census, the Ambarvalia in May, the Amburbium in February, and other similar lustrations. It

derived its name from the three animals of which it consisted, a boar, a ram, and a bullock. In all cases the animals were led three times around the gathering or territory to be purified, and then sacrificed.

SUPAN, sōō'pän, ALEXANDER (1847—). An Austrian geographer, born at Innichen, Tyrol. Having studied at the universities of Gratz, Vienna, Halle, and Leipzig, and taught at Laibach, he qualified as privat-docent at Czernowitz, Bukowina, and was made professor in 1880, but removed to Gotha in 1884 to assume the redaction of *Petermanns Mitteilungen*. The publication of its geographical literary reports, since 1885, is due to his initiative. He wrote: *Lehrbuch der Geographie für oesterreichische Mittelschulen* (1874; 10th ed. 1901); *Grundzüge der physischen Erdkunde* (3d ed., 1903); *Geographie von Oesterreich-Ungarn* (1889); *Deutsche Schulgeographie* (6th ed. 1903); and numerous contributions to the *Mitteilungen*.

SUPEREROGATION, WORKS OF (Lat. *supererogatio*, payment in addition, from *supererogare*, to pay in addition, from *super*, above + *erogare*, to expend, especially after asking consent, from *e*, out + *rogare*, to ask). A class of good works which, in the Roman Catholic system, are described as not absolutely required of each individual as conditions to his eternal salvation. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counseled. (See EVANGELICAL COUNSELS.) For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is indispensably necessary; and they do not ascribe to them any merit, except that which arises from God's own free and gratuitous promise. A further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another; and hence, in the Catholic theory of indulgences (q.v.), along with what they regard as the infinite and inexhaustible treasure of the merits of Christ, they also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that 'treasure of the Church' which is applied in the form of indulgences.

The idea of such works is rejected by Protestants generally, and the Anglican Articles declare that they "cannot be taught without arrogancy and impiety."

SUPERFICIES (Lat., surface). At civil law, the hereditary and alienable right to maintain and use a building on land belonging to another. Unless a term be fixed in the contract, the right is perpetual. The owner of the land is technically owner of the building (*superficies solo cedit*); but practically the owner has no right except to an annual ground-rent (*solarium*). Even when the ground-rent has not been paid for several years, the right of the superficiary is not forfeited unless this be expressed in the contract. In the absence of such express agreement, the owner of the land can only attach and sell the superficiary right.

Historically, *superficies* was first established at Rome in public or municipal land. It was originally lease (*locatio conductio*), but it soon became a different thing, because the superficiary was recognized as having possessory right (see POSSESSION) and actions *in rem*.—advantages which the Roman lessee did not enjoy. In the later development of the Roman law superficiary right could be established on private land and also in a special story or floor of a building.

Superficies is analogous to *emphyteusis* (q.v.), but the rights of the superficiary are greater than those of the emphyteutist.

Mediæval jurists regarded superficies and emphyteusis as cases of divided ownership, analogous to the feudal tenures. The landlord had *dominium directum*, the tenant *dominium utile*. Some of the modern legislations recognize divided ownership in a different sense: the landlord is said to own the land, the superficiary the house or floor. See DOMINIUM; EMPHYTEUSIS; PROPERTY.

SUPERFŒTATION (from Lat. *superfœtare*, to conceive anew when already pregnant, from *super*, above, over + *fœtare*, to breed, from *fœtus*, offspring; connected with Gk. *φύειν*, *phyein*, to generate, Skt. *bhū*, to become, and ultimately with Eng. *be*), and SUPERFECUNDATION. The circumstance of two distinct conceptions occurring in the same woman at an interval of weeks or months, so that two fœtuses of different ages, and possibly the offspring of different fathers, may coexist in the uterus. True superfœtation takes place when a second ovule has been impregnated while the uterus already contains an ovum which has arrived at a considerable degree of development. By *superfecundation* is meant the impregnation, at or near the same period of time, of two separate ovules before the decidua lining of the uterus has been formed, which is believed by many to interpose an insuperable obstacle to subsequent impregnation. The possibility of this occurrence has been proved on numerous occasions by the birth of twins bearing the stamp of fathers of different races, i.e. white and black. The question of superfœtation has given rise to much discussion owing to its medico-legal importance. Against the possibility of this occurrence it is urged that ovulation is suspended when impregnation has taken place; that the decidua (afterbirth) so completely fills the uterine cavity that the passage of spermatozoa is impossible, and that their ascent is prevented by the plug of mucus filling the cervix. It is now believed that none of these obstacles is insuperable.

The medico-legal aspect of the question may be summed up as follows: A woman may be unjustly suspected of conjugal infidelity when, delivery of a mature or premature child having taken place, she is (without having meanwhile seen her husband, or submitted to coitus), in the course of one, two, or three months, delivered of another child, either mature or premature. Cases of this kind may be explained, as indicated above, by twin pregnancy with expulsion of the fœtuses at an interval of several weeks or months; by the existence of bilobed uterus, the two cavities expelling their contents at different times; or by true superfœtation. When the children are of different race or color the fidelity of the female may be justly questioned. See Bonner, in *Edinburgh Medical Journal* (1864-65); Witthaus and Becker, *Medical Jurisprudence* (New York, 1894); Playfair, *Midwifery* (Philadelphia, 1893).

SUPERIOR. A port of entry and the county-seat of Douglas County, Wis., adjacent to Duluth,

Minn.; at the mouth of the Saint Louis and Nemadji rivers, on three bays, inlets of Lake Superior, and on the Northern Pacific, the Eastern Minnesota, the Saint Paul and Duluth, the Duluth, South Shore and Atlantic, the Great Northern, and the Chicago, Saint Paul, Minneapolis and Omaha railroads (Map: Wisconsin, A 2). It is connected with Duluth by two railroad bridges and by ferry. The city is finely situated. It is the seat of a State Normal School, and among other features are a public library, with more than 13,000 volumes, and Saint Mary's Hospital. An excellent harbor, which has been enlarged and improved through national, State, and city appropriations, and good transportation facilities have contributed to Superior's commercial importance. In the year ending June 30, 1901, the total foreign trade was valued at $7,353,553, including exports to the amount of $6,946,547. Wheat, corn, flour, lard and other meat products, iron and steel, cement, and lumber compose the principal shipments. The various industries in the census year 1900 had an invested capital of $5,882,562, and a production valued at $7,527,703. There are lumber mills, foundries and machine shops, breweries, flour mills, boiler shops, iron works, manufactories of chairs and windmills, and shipbuilding interests.

The government is vested in a mayor, elected biennially, and a unicameral council; and in administrative officials, the majority of whom are appointed by the mayor, subject to the confirmation of the council. For maintenance and operation, the city spends annually about $409,000, the chief items being: schools, $120,000; fire department, $25,000; interest on debt, $23,000; and streets, $19,000. Population, in 1890, 11,983; in 1900, 31,091.

On the site of Superior Radisson and Grosseilliers are supposed to have made their headquarters in 1661. Here in 1680 the famous explorer Du L'Hut established a trading post. Superior was first laid out in 1855, and in 1885 the city was considerably enlarged, a company headed by Gen. J. H. Hammond having laid out an addition west of the original town. In 1881 the Northern Pacific Railroad Company built a branch hither.

SUPERIOR, LAKE. The largest and most northerly of the Great Lakes of North America, and the largest body of fresh water in the world (Map: America, North, K 5). It is situated a little to the northeast of the centre of the continent, and is bounded on the north and east by the Canadian Province of Ontario, and on the south by the State of Michigan and a part of Minnesota, the latter State forming also the western boundary. Its shape is nearly a crescent, the horns extending southwest and southeast, while the large Keweenaw Peninsula reaches nearly to the centre of the lake from the middle of the southern coast. Lake Superior has a coast line of 1500 miles; its extreme length from east to west is 412 miles; its extreme breadth is 167 miles. Area, 31,200 square miles. Its mean elevation above sea level is 602 feet, and it lies 20 feet above the level of Lake Huron, into which it discharges through the Saint Mary's River (q.v.). It receives a large number of streams, but they are all short, the lake being closely hemmed in by the watersheds of the Mississippi and of Hudson Bay. The principal stream entering it is the Saint Louis River, which falls into the extreme western end of the lake, and is considered as the farthest headstream of the Saint Lawrence.

The shores of Lake Superior, except in the southeast, where there are long lines of sand dunes, are generally bold and rocky. On the Michigan shore are the celebrated sandstone cliffs known as Pictured Rocks, which are streaked by the red and yellow deposits of ferruginous waters. In many places, especially along the Canadian shore, there are precipitous cliffs of basalt rising directly from the water to a sheer height of from 300 to over 1000 feet, such as Thunder Cape on the northwest shore. The north shore is also cut up into deep bays surrounded by high cliffs, and forming good harbors, and it is lined with a number of high, rocky islands with precipitous sides and capped by eruptive material. In the greater part of the lake, however, the islands are few, the largest being Isle Royal, 45 miles long and 8 miles wide, belonging to Michigan. In general the country surrounding the lake is covered with pine forests.

Lake Superior is deeper than any of the other Great Lakes, its maximum depth being 1008 feet, so that the bottom lies 400 feet below sea level. The water is very clear, and so fresh as to be almost chemically pure. It is cold throughout the year to within a few feet of the surface, and in the deeper portions maintains a nearly uniform temperature of 39°. The lake never freezes except in the shallow water along the shores. The level of the lake is subject to several sets of periodic changes, partly owing to changes in rainfall and evaporation and partly to the winds; a long continued storm will sometimes raise the leeward level seven feet above the normal. Violent storms occasionally sweep over the lake, when the waves may attain an amplitude of 15 or 18 feet.

The basin of Lake Superior is remarkable as being unrelated to those of the other Great Lakes. While the latter are river valleys scooped out of the softer strata of the ancient coastal plain lying northwest of the Appalachian Plateau and skirting the Archæan continent, Lake Superior lies almost wholly within the Archæan region. The most recent investigators are of the opinion that this basin is a primitive depression in the earth's crust antedating the Huronian period. The numerous intrusions of eruptive rocks which encircle the lake are arranged roughly in concentric circles, the most recent being found nearest the lake, and it has been suggested that the depression is an ancient and deep-seated centre of volcanic activity. The formation of the lakes themselves, however, is due to the obstruction of the valleys during the Glacial Period. The country surrounding the lake is rich in minerals, and large veins of copper and iron ore traverse its bottom from the southern shore. Consult Agassiz, *Lake Superior: Its Physical Character, Vegetation, and Animals* (Boston, 1850). For commerce and navigation on the lake, see GREAT LAKES.

SUPERPHOSPHATE. An orthophosphate in which only a portion of the hydrogen of the orthophosphoric acid has been replaced by a basic radical. The most important superphosphate, agricultural, that of lime, monocalcium phosphate ($CaH_4O_2.2H_2O.P_2O_5$), is prepared by treating trical[illegible] phosphate ($[CaO]_3.P_2O_5$) in the form

of mineral phosphate, bone ash, bone black, etc., with sulphuric acid. It is also called acid phosphate. See MANURES AND MANURING.

SUPERPOSITION. See CONGRUENCE.

SUPERSEDEAS (Lat., that you set aside). A common-law writ containing an order for a stay or suspension of legal proceedings. Under the common-law practice it is issued in a great variety of cases for the above purpose, and is sometimes used as a substitute for the common-law writ of *audita querela* (q.v.). Probably it is issued most frequently to stay execution, pending an appeal from a judgment. The person applying for the writ is required to give a bond, to secure the other party against loss by reason of the delay. Several writs are said to operate as a *supersedeas* by implication, as in effect they operate as a stay, viz.: habeas corpus, certiorari, and writ of error. The practice of granting a *stay* by an order of the court has superseded the above practice in many jurisdictions.

SUPERSTITION (Lat. *superstitio*, excessive religious belief, superstition, possibly originally a standing over a thing in amazement or awe, from *superstare*, to stand above or over, from *super*, above, over + *stare*, to stand). A term loosely used to include all false faith or belief, its distinguishing characteristic being its irrational estimate of something imperfectly understood. Since the answer to the question of truth or falsity varies with place and time, it follows that the accepted belief of one time or people may be superstition to another. Most of the popular superstitions of the present are survivals of earlier science or religion. At a time when there existed no system of recorded observations of natural phenomena conclusions were of necessity drawn from external characteristics, and objects and events were supposed to exercise influences corresponding to the impression produced upon the senses or imagination. This manner of interpretation, or sympathetic magic (see MAGIC), is responsible for a great mass of superstitions. It is a characteristic of popular credulity that such notions, once prevalent, do not yield to contrary experience. If observation shows the principle to be inaccurate, reasons are always at hand to explain the error, or at the most it is only necessary to introduce additional complexity into the rule. Hence the power of the ancestral habits, which we find arbitrary and call superstitious. With all savage peoples, such beliefs have an immense effect on action; the daily method of nutrition, attire, the chase, agriculture, and warfare are determined by an infinity of regulations which are religiously handed down from generation to generation. In some cases it is possible to discover the principle of expediency which gave birth to the requirement; thus, the discovery of the ill effect of in and in breeding causes to be established a religious necessity, limiting the relations of the sexes according to certain complicated and ingenious rules, of which the prohibited degrees are the modern ecclesiastical survival. But in multitudes of other cases no good reason can be offered for demands and abstentions which originally depend on inferences which it is impossible to reconstruct.

A considerable number of superstitions are connected with the heavenly bodies. From remote times the observation of the stars and their movements has been considered important, but it has been with the night, especially, that ancient religious ceremonies are associated. The most distinctive differences between the nights were formed by alterations in the growth of the lunar crescent; according to universal processes of thought, it was supposed that the time when the planet increases and becomes dominant the principle of growth must prevail, and on the other hand, that her wane must be a season of general decay. Hence it has been everywhere inferred that all operations designed to promote increase ought to be performed at the time of the new moon, and that then potatoes should be planted, hair cut, and so on. But if it is desired to cause shrinking, the work should be done when the moon is at the full according to the maxims of traditional agriculture, and at this time should be cut alders, spruce, and other undergrowth, because the roots will in this case wither without sprouting.

Not less important in popular usage is the part played by the course of the sun. As he moves in a particular direction, so it has been thought that in order to produce beneficial results, mankind should proceed in a corresponding manner; in worship it was thought necessary to adopt a processional movement in the sunwise direction. Even in the ordinary movements of daily life this order was followed, and traces of it survive to the present day. Thus in order to make good bread or butter, it is essential that the motion should be in the same uniform direction, for reversal of the direction in which the kneading or churning is performed will undo the work accomplished, and insure a failure. From household maxims still preserved, it appears that the hand must be moved in a sunwise circuit. As the route taken by the sun is holy, so the opposite path will be evil, and has been adopted in practices of witchcraft and magic, and in Roman worship the gods below were adored with this reverse circuit.

Among periods of human life, the terror which attaches to death has made it the centre of a vast body of superstitious habits. A great number of actions and experiences are still popularly regarded as signs of approaching departure. The principle on which the phenomena are interpreted is that of association of ideas. Thus ringing in the ears is a sign of dissolution, because the Church has usually rung a 'death-bell' over the departed; carrying a spade through the house has like significance, because a spade is used to dig graves; a blue flame in the candle is ominous, for the lowering of the light forecasts the decline of the life; a flower blooming out of season foreshows a decease; and so on indefinitely. In like manner, the unusual also is a fruitful source of superstition; if every child were born with a caul (that is, a membrane encompassing the head) it is doubtful if this would have been taken as an especial sign of good luck.

A considerable number of superstitions relate to times of the year, and revert to the practices of old religion. Thus Hallowe'en, or the evening before All Saints' Day, is attended with observances which seem to have been dependent on its original character as a feast of the dead, when departed spirits were invited to partake in the fruits of the harvest, and were conceived as present at the sacrifice and merry-making. On this

night it is usual to perform divinations, now reduced to mere jests, in which an unmarried person is expected to discover his or her companion for life. These practices must be regarded as the remainder of serious necromancy, in which the returning spirits were asked to reveal the future.

While the majority of superstitions are remains of antiquity, their invention has not altogether ceased in historical times. Of this we have examples in the prejudice against the number thirteen, and in objection to Friday as unlucky, since in Christian thought the day of the Crucifixion and the number involving the addition of Judas were of necessity regarded as ill-omened. The superstition of the evil eye, that is, the belief that certain individuals have the power to injure by a look, is still widespread in Eastern countries, where the belief yet lingers that the demoniac (q.v.) is divinely inspired. Nature worship (q.v.) lingers in such superstitions as those connected with the moon, the belief in its mysterious power to work good or ill, its influence on the weather, and the like. The belief in ghosts (q.v.) reflects the earlier ancestor worship. The common notion about the good luck brought by a horseshoe has been traced back to phallicism (q.v.).

The following list, prepared by Bolton (*The Counting-out Rhymes of Children*, London, 1888), gives the technical names for different forms of divination and the method followed in each:

Aëromancy	by appearances in the air.
Alectoromancy, or Alectryomancy	by a fowl picking up grains of wheat.
Aleuromancy	by wheat.
Alphitomancy	by barley flour.
Amniomancy	by the amnion.
Anagrammatism	by anagrams of a person's names.
Anthropomancy	by human entrails.
Anthroposcopy	by man's features.
Arithmancy	by the use of numbers.
Astragalomancy, or Astragiromancy	by little sticks, bones, tablets, or dice.
Astrology	by the heavenly bodies.
Austromancy	by winds.
Axinomancy	by the axe or hatchet.
Belomancy	by arrows.
Bibliomancy	by the Bible.
Bletonism	by subterranean springs.
Botanomancy	by herbs.
Cartomancy	by playing cards.
Capnomancy	by smoke from an altar.
Catoptromancy	by mirrors.
Ceromancy	by dropping melted wax into water.
Cephalomancy	by an ass's head.
Chalcomancy	by vessels of brass.
Chaomancy	by appearances in the air.
Chartomancy	by writings on paper.
Chiromancy	by the hand.
Cledonismancy	by certain lucky or unlucky words.
Cleromancy	by dice.
Clidomancy	by keys.
Coscinomancy	by sieves.
Crithomancy	by dough of cakes.
Cromniomancy	by onions.
Crystallomancy	by a magic lens.
Dactylomancy	by suspended rings.
Demonomancy	by evil spirits.
Daphnomancy	by the laurel.
Extispicium	by entrails of a victim.
Gastromancy	by ventriloquism, or by a vial of water.
Geloscopy	by the manner of laughing.
Geomancy	by geometrical figures.
Gyromancy	by walking in a circle.
Haruspicy	by sacrificial appearances.
Halomancy	by common salt.
Hieromancy	by the entrails of animals.
Hydromancy	by water.
Hydatoscopy	by rain water.
Ichthyomancy	by the entrails of fishes.
Idolomancy	by idols and images.
Judeomancy	by a Jewish art.
Keraunoscopy	by thunder.
Lampadomancy	by lamps.
Lecanomancy	by a basin of water.
Libanomancy	by incense.
Lithomancy	by precious stones, or pebbles.
Logarithmancy	by logarithms.
Lychnomancy	by lamps.
Margaritomancy	by pearls.
Macharomancy	by knives and by swords.
Meteoromancy	by meteors.
Metoposcopy	by men's features.
Molybdomancy	by melted lead.
Myomancy	by mice.
Necromancy	by the black art.
Oinomancy	by wine of libations.
Omphalomancy	by the navel of an infant.
Oneiromancy	by dreams.
Onomancy	by letters forming the name of a person.
Onyomancy, or Onychomancy	by the finger nails reflecting the sun's rays.
Oöscopy	by eggs.
Ophiomancy	by serpents.
Ornithomancy	by birds.
Palmistry	by the hands.
Palpitatio	by the pulsation of some member.
Pegomancy	by springs of water.
Pessomancy	by pebbles.
Physiognomy	by man's features.
Podomancy	by the feet.
Psephomancy	by pebbles drawn from a heap.
Psychomancy	by ghosts.
Pyromancy	by sacrificial fire.
Pyroscopy	by examining fire.
Rhabdomancy	by wands.
Rhapsodomancy	by poetical passages.
Salisatio	by the pulsation of some member.
Sciomancy	by shadows or manes.
Sideromancy	by straws on a red-hot iron.
Sortilege	by drawing lots.
Spatilomancy	by skin, bones, etc.
Stereomancy	by the elements.
Sternomancy	by marks on the breast.
Stichomancy	by poetical passages.
Tephramancy	by writing in ashes.
Theomancy	by oracles.
Theriomancy	by wild beasts.
Tyromancy	by cheese.

See also FOLKLORE; MAN, SCIENCE OF; MAGIC; MYTHOLOGY; RELIGION, COMPARATIVE.

SUPERTONIC. In music, the note which, in the diatonic scale, is next above the tonic or keynote, and forms with it the interval of the second, as, for example, D in the key of C major.

SUPERVISOR (ML. *supervisor*, overseer, from Lat. *supervidere*, to overlook, oversee, from *super*, above, over + *videre*, to see). A popularly elected officer of a township or other local district in the United States. The name first appeared in New York in 1691. This officer is still the chief administrator of the town organization in New York, while all the supervisors of the county assembled in a board meeting constitute the chief county authority. The New York supervisor system exists in several Western States. In Michigan and Illinois, as in New York, there is a single supervisor for each township, while in Wisconsin and Minnesota there are three for each township. In some States the supervisor is not a member of the county board and his duties vary, as, for example, in Michigan, where he is also tax assessor, and in Illinois, treasurer. See UNITED STATES, section on *Local Government*.

SUPPÉ, sōō-pā', FRANZ VON (1820-95). An Austrian composer of light opera, born at Spalato, Dalmatia. He studied at the Vienna Conservatory under Sechter and Seyfried. He was kapellmeister successively at the Josephstädter Theater, the Theater an der Wien, and from 1865 until the end of his career at the Leopoldstädter Theater. He was a prolific composer, the most important of his works being the operettas Flotte Bursche (1863), Die schöne Galathea (1865), Leichte Kavallerie (1866), Banditenstreiche (1867),

Fatinitza (Vienna, 1876), *Boccaccio* (1879), *Das Modell* (posth., 1895). He also composed considerable instrumental and sacred music. He was one of the most popular of the world's light opera composers, and a musician of no little genius.

SUPPLE JACK (*Berchemia volubilis*). An American twining shrub of the natural order Rhamnaceæ, which is found as far north as the Dismal Swamp in Virginia. It has oval leaves, small flowers, and violet-colored berries, and ascends to the top of the highest trees. The name is also given in the West Indies and tropical America to Serjania lucida and Serjania trachygona, shrubs of similar habit which belong to the natural order Sapindaceæ. The stems are used for walking-sticks.

SUPPLEMENTARY PROCEEDINGS. Certain proceedings under codes and practice acts designed to discover property of a judgment debtor and apply it to the satisfaction of the judgment. The order directs the debtor to appear and submit to an examination under oath as to his property. Most acts provide for the appointment of a receiver where property is found. Consult *New York Code of Civil Procedure*. See EXECUTION.

SUPPLIANTS, THE (Lat. *Supplices*, Gk. Ἱκέτιδες, *Hiketides*). (1) The earliest of the extant plays of Æschylus, of uncertain date. With but slight plot or dramatic action, it pictures the arrival of the fifty daughters of Danaüs on the shore near Argos, their prayer to the King of Argos for protection, the appearance of the ship bearing the fifty sons of Ægyptus, and their repulse by the King.

(2) A tragedy by Euripides, produced about B.C. 420. Theseus and the Athenians, entreated by the mothers of the dead chiefs, after defeating the Thebans, oblige them to surrender the bodies of the slain Polynices and his allies, to whom they had refused burial. The funeral of the chiefs, the burning of Evadne on the pyre of her husband, Capaneus, and the patriotic and political references provide the interest lacking in the simple plot.

SUPPORTERS (from *support*, OF., Fr. *supporter*, from Lat. *supportare*, *subportare*, to support, from *sub*, under + *portare*, to carry). In heraldry, figures placed on each side of an armorial shield. See HERALDRY.

SUPPOSITORY (Lat. *suppositorium*, from *supponere*, *subponere*, to put beneath, from *sub*, under + *ponere*, to put, place). A solid medicated compound intended to be introduced into the rectum, vagina, or urethra, either for the purpose of causing an evacuation of the bowels, or for its specific effect on inflamed mucous membrane. Suppositories are made in several shapes —conical, cylindrical, or spherical—and in sizes adapted to the orifice they are intended to enter. In consistency they are such that they remain solid at ordinary temperatures, but melt slowly at the temperature of the body. The basis of most suppositories is cocoa butter. With this are incorporated one or several ingredients, such as carbolic acid, tannic acid, belladonna, morphine, opium, cocaine, and lead.

SUPPURATION (Lat. *suppuratio*, *subpuratio*, from *suppurare*, *subpurare*, to form pus, from *sub*, under + *pus*, white viscous matter from a sore). A morbid process which takes place in animal tissues, resulting in the formation of pus. It is a frequent termination of inflammatory processes and is due to invasion of the inflamed tissues and their exudates by pyogenic organisms. (See PUS; INFLAMMATION.) White blood cells escape into the neighboring tissue after passing through the walls of the blood vessels, and become pus cells. If they escape to the surface and there is an open wound, the wound is said to suppurate. If they are confined to a circumscribed area below the surface, the collection of pus cells and broken down tissue is called an abscess (q.v.).

SUPRALAPSARIAN. See INFRALAPSARIAN.

SUPRARENAL (from Lat. *supra*, above + *renalis*, relating to the kidneys, from *renes*, kidneys) **CAPSULES AND THEIR DISEASES.** The suprarenal capsules are two small, flattened, glandular bodies of a yellowish color and crescentic shape, situated, as their name implies, immediately in front of the upper end of each kidney. In weight they vary from one to two drams. They belong to the class of ductless glands, and on making a perpendicular section each gland is seen (like the kidney) to consist of cortical and medullary substance. The blood-vessels and nerves of the glands are exceedingly numerous. The capsules are also called the suprarenal bodies or the adrenals.

The suprarenal bodies are subject to inflammation, to atrophy, and to invasion by malignant processes, but all of these occurrences are extremely rare. The only morbid process that occurs with any frequency is tuberculosis. This process is the causative factor in the production of Addison's disease (q.v.), a rather rare and usually fatal affection characterized by anæmia, general languor, feebleness of the heart's action, irritability of the stomach, and bronzing of the skin.

The dried and prepared suprarenal substance of animals constitutes a powerful and valuable astringent and hæmastatic. See ORGANOTHERAPY.

SUPREMACY, ROYAL (OF. *suprematie*, Fr. *suprématie*, from OF. *supreme*, Fr. *suprême*, supreme, from Lat. *supremus*, highest, superlative of *superus*, high, from *super*, Gk. ὑπέρ, *hyper*, Skt. *upari*, Goth. *ufar*, OHG. *ubar*, *uber*, *ubiri*, AS. *ofer*, Eng. *over*). A phrase specifically applied to the relation of the sovereign of England to the established Church of that country. During the Reformation the supremacy of the Pope was abolished in England, and the act passed in 1534 declared the King to be the "only supreme head on earth of the Church of England." The Government at the same time issued an explanation of this language to the effect that it was intended to recognize in the sovereign the authority of a governor without spiritual jurisdiction, and not to "take any power from the successors of the Apostles that was given them by God." Under Queen Mary this Act of Supremacy was repealed in 1554, but this repeal was itself repealed by Queen Elizabeth in 1559, who, however, did not make use of the words 'supreme head.' In her injunctions she explained the supremacy of the Crown to be "that which is and was of ancient time due to the Imperial Crown of this realm, that is, under God to have the sovereignty and rule over all manner of persons born within those her realms of what

estate either ecclesiastical or temporal soever they may be so as no other foreign power shall or ought to have any superiority over them." The governing and visitorial power of the sovereign, under the safeguard of an organized court of justice, has since been continuously recognized by the Church of England. By successive statutes an oath as to royal supremacy was appointed to be taken by the holders of public offices along with the oaths of allegiance and abjuration. A royal supremacy similar in character is a prerogative of the Czar of All the Russias, also of the Protestant princes of Germany, and of the sovereigns of Holland, Denmark, Norway, and Sweden.

SUPREME COURT. See COURT.

SUPREME COURT OF THE UNITED STATES, THE. The Supreme Court of the United States is the head of the national judiciary. In our system of government there are three coördinate departments—executive, legislative, and judicial. The latter is the last named in the national Constitution, was the last brought into being, but is by no means the least important. The existence of the Supreme Court is authorized by the Constitution. Section 1 of Article III. provides that "the judicial power of the United States shall be vested in one supreme court, and in such inferior courts as the Congress may from time to time ordain and establish." The Supreme Court is thus a constitutional court, while the other courts of the United States are statutory. Though the Constitution provides for a Supreme Court, it leaves its organization and membership for Congressional supervision. The first act in respect thereto was passed at the first session of the United States Congress, approved by Washington on September 24, 1789, and directed that the court should consist of a Chief Justice and five associate justices, any four of whom should make a quorum. This act not only made provision for the Supreme Court, but created the inferior courts of the United States and organized its entire judicial system. It was drafted by Oliver Ellsworth, afterwards a Chief Justice of the United States. It has remained in its main features unchanged, and one of Ellsworth's admirers has declared that the Federal judicial system, "the whole edifice, organization, jurisdiction, and process, was built by him as it now stands."

The Constitution in Section 2 of Article III. declares that "the judicial power shall extend to all cases, in law and equity, arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority; to all cases affecting ambassadors, other public ministers, and consuls; to all cases of admiralty and maritime jurisdiction; to controversies to which the United States shall be a party; to controversies between two or more States; between a State and citizens of another State; between citizens of different States; between citizens of the same State claiming lands under grants of different States, and between a State, or the citizens thereof, and foreign citizens, or subjects." And also that "in all cases affecting ambassadors, other public ministers, and consuls, and those in which a State shall be party, the Supreme Court shall have original jurisdiction. In all the other cases before mentioned, the Supreme Court shall have appellate jurisdiction, both as to law and fact, with such exceptions and under such regulations as the Congress shall make." The original jurisdiction, being conferred by the Constitution, cannot be taken away by Congress, although that body may prescribe the procedure by which that jurisdiction is to be exercised; but in respect to the appellate jurisdiction both the procedure and its extent are matters of Congressional determination, and Congress has from time to time made changes in each.

The appellate jurisdiction may be separated into two divisions: one over State courts; the other over the inferior Federal courts. With respect to the former it reviews the final judgment rendered in any case by the highest court of the State to which the case under State practice can be carried, and this irrespective of the amount in controversy. With respect to the latter, up to 1891 it had, speaking generally, jurisdiction to review the proceedings in any case which had passed to final judgment in such inferior courts, with a limitation in some classes of cases to a certain amount in controversy. By the act of that year (1891) courts of appeal were established, one in each circuit, and were given final jurisdiction in certain cases, such as revenue, admiralty, patent cases, etc. But the Supreme Court may still by certiorari, if it sees fit, bring any of these cases from a court of appeals before it for review. This act did away with the limitation as to the amount in controversy requisite for review by the Supreme Court. In addition the Supreme Court is given power to issue writs of prohibition and all other writs which may be necessary for the exercise of its jurisdiction and agreeable to the principles and usages of law. So that it may be said that the Supreme Court has complete supervision and control over all the inferior courts of the United States.

The full significance of the Supreme Court as a factor in the new government was not at first appreciated by all; yet there were some who realized its great importance, like Washington, who, with prophetic visions of what the future was to disclose, wrote, in a letter inclosing the commission of James Wilson, one of the first associate justices: "Considering the judicial system as the chief pillar upon which our national government must rest, I have thought it my duty to nominate for the high offices in that department such men as I conceived would give dignity and lustre to our national character." Early there arose two parties in this country—one believing that the new government was but a continuance of the old confederacy, in effect a league of States, the States remaining the dominant powers, and the national Government serving only as a limited agency for the transaction of a few matters of general importance; the other that a new nation was created, supreme in control, possessing all the power of a nation, the States being simply parts of the one new nation. By the one party, the provisions of the Constitution were strictly construed; no power was vested in the national Government, except that which was expressly named. The other believed that the Constitution was to be so construed as to give vigor and efficiency to the new nation. Upon the solution of this question turned the future of the Republic. It was finally answered

and settled by the Supreme Court, which has always spoken for the nationality of the United States. A brief reference to some of the leading cases may indicate its action, and the effect thereof on our history. In Chisholm, executor, *v.* Georgia, 2 Dall. 419, decided February 18, 1793, the court (considering those provisions of the Constitution which extend the judicial power of the United States to controversies "between a State and citizens of another State," and give to the Supreme Court original jurisdiction of controversies to which a State is a party) held that an action might be maintained against a State by a citizen of another State. The national idea was not yet strong, and the proposition that a sovereign State could at the instance of an individual and without its consent be brought to the bar of a court and compelled to defend an action against it startled many. As a consequence the Eleventh Amendment was adopted, which in effect forbids an action in the Federal courts against a State by an individual.

John Marshall became Chief Justice in January, 1801, and remained in office for thirty-four years. He is often aptly called 'the great Chief Justice.' During his long term many questions of vital interest were considered and determined by the court. It was a great constructive period, and by those decisions which declared the relative powers of the nation and the State was disclosed the full significance of the Constitution as an instrument expressing the creating of a new nation and not a mere article of confederation between separate States. Not merely were these relative powers declared, but the peculiar work and value of the Supreme Court as the tribunal to determine the extent of such relative powers and to pass in judgment upon acts of State and nation were also made apparent. In Marbury *v.* Madison, 1 Cranch, 137, decided February 24, 1803, it was held that an act of Congress repugnant to the Constitution was void. True, this was not the first case in which such a judicial opinion had been announced, but Chief Justice Marshall presented the argument so fully and forcibly that since then the question has been at rest, and it is now undoubted that a legislative act repugnant to the Constitution is a nullity. Again, in M'Culloch *v.* Maryland, 4 Wheat. 316, the question was presented of the power of Congress to charter a national bank. The Constitution gives in terms no such power, or indeed any power to create corporations, and the advocates of a strict construction contended that in the absence of an express grant of such power Congress could not create a corporation for any purpose. The court, upon the authority of that clause which, following the clauses making express grants to Congress, empowers that body to "make all laws which shall be necessary and proper for carrying into execution the foregoing powers," held that, as a bank was a proper and convenient agency for carrying on the fiscal affairs of a government, there was power in Congress to create a banking corporation; that the word 'necessary' was not to be construed in a strict and narrow sense, but—viewing the Constitution as an organic instrument by which a government was established and which from the very necessities of the case used general terms in giving to that government the power essential for its being—to be taken broadly and liberally, and said in a phrase which has become axiomatic in constitutional law: "Let the end be legitimate, let it be within the scope of the Constitution, and all means which are appropriate, which are plainly adapted to that end, which are not prohibited, but consistent with the letter and spirit of the Constitution, are constitutional."

This decision laid the foundation of what is known as the doctrine of implied powers, the significance of which may be better appreciated when we recall the fact that under a grant of power stated in these few words "to establish post-offices and post roads" the great postal system of the United States has been built up. At the same term was decided the case of the Trustees of Dartmouth College *v.* Woodward, 4 Wheat. 518, in which it was held that the charter of a private corporation granted by a State created a contract whose obligations the State could not impair, because of that provision of the Federal Constitution which forbids a State to pass any law "impairing the obligation of contracts." (See DARTMOUTH COLLEGE CASE.) It is true the full effect of that decision has been avoided by constitutional enactments in the several States, reserving the power of repeal, alteration, and amendment of all corporate grants. Yet, notwithstanding these limitations, that decision stands as the great bulwark of the sanctity of contract rights created by the States.

Martin *v.* Hunter, 1 Wheat. 304, and Cohens *v.* Virginia, 6 Wheat. 264, the latter decided at the February term, 1821, settled the power of the Supreme Court to review, and if necessary set aside, the proceedings of a State court in a case in which a Federal right was asserted by the defeated party. Thus it is that all rights which are claimed under the Constitution of the United States may finally be adjudicated by the Supreme Court of the United States, and a unity is thereby established which pervades the nation in respect to such rights. Again, in Gibbons *v.* Ogden, 9 Wheat. 1, decided in 1824, the supreme power of the Federal Government over the navigable waters of the United States was affirmed. In that case Robert Fulton, the inventor of the steamboat, and his associate, Robert R. Livingston, obtained from the State of New York the grant of an exclusive right to navigate with steamboats the waters within the jurisdiction of that State. Gibbons claimed a right under national authority to navigate with his steamboats the same waters, and hence the litigation. The Constitution having granted to Congress the power to "regulate commerce with foreign nations and among the several States," it was held that that power could not be infringed upon by any action of a State and that a State could not interfere with such commerce even when carried upon waters wholly within its own territory. Upon that decision rests that freedom of commerce between the States which, perhaps more than any other thing, has wrought into the minds of the people the great thought of a single controlling nationality. In this connection the case of 'The Genesee Chief,' 12 How. 443, decided in 1851, may be noticed. In that case it was held that the English rule that the jurisdiction of admiralty ended with tide waters was inapplicable, and that in this country such jurisdiction, which by the Constitution is vested in the United States courts, extends to all the navigable waters of the Republic. Thus

the control of the Great Lakes and all the navigable rivers of the United States, whether within or without the limits of a State, is vested in the national Government. In Osborn *v.* United States Bank, 9 Wheat. 738, it was held that a State had no power to tax one of the branches of the United States Bank; that the bank was one of the agencies and instrumentalities of the national Government, and as such was removed from the sphere of State taxation. From that decision has sprung the settled rule exempting all the agencies and instrumentalities of the national Government from State taxation except so far as permitted by Congress. This is seen in respect to United States bonds, national banks, etc. Conversely, though at a later date, in The Collector *v.* Day, 11 Wall. 113, decided December, 1870, it was held that Congress could not impose an income tax on the salaries paid to State officials. By these two decisions neither State nor nation can impair the efficiency of the necessary governmental action of the other.

Chief Justice Marshall was succeeded by Chief Justice Taney. As he and a majority of his associates had belonged to the 'strict construction school,' many prophesied a complete reversal of prior rulings, but the court still affirmed the nationality of the United States. Thus in Pennsylvania *v.* Wheeling and Belmont Bridge Company, decided in 1849, 9 How. 647, and 1851, 13 How. 518, the jurisdiction of the Supreme Court was affirmed over a case brought by a State to restrain the obstruction of a navigable river within the limits of other States. In Ableman *v.* Booth, decided in 1858, 21 How. 506, a prisoner in custody of the United States authorities was held not to be subject to discharge by State process. And in the famous 'Dred Scott Case,' decided in 1856, 19 How. 393, the nationality of the United States was asserted, though in a way not satisfactory to the friends of human freedom, in that it decided that the recognition by the Constitution of slave property carried with it the protection of that property in all the territories of the nation.

When the Civil War ended and Chief Justice Taney had been succeeded by Chief Justice Chase a new series of cases arose. Naturally bitter feelings were excited by the war, and stringent laws were passed by Congress and by some of the States against those who had participated in the rebellion. Test oaths were prescribed which prevented ministers and lawyers who had taken part with the South from pursuing their respective professions, but in Cummings *v.* Missouri, and *ex parte* Garland, decided in 1866, 4 Wall. 277 and 333, such test oaths were adjudged invalid as *ex post facto* acts. At the same time, in *ex parte* Milligan, 4 Wall. 2, it was held that a military tribunal, sitting in Indiana, a State in which there had been no rebellion, had no jurisdiction to punish a citizen, in no way connected with the army, for an offense against the Government. In Texas *v.* White, 7 Wall. 700, decided in 1868, it was held that States in rebellion did not lose their existence or identity, and in the opinion Chief Justice Chase made the memorable declaration that this was "an indestructible union composed of indestructible States." Soon after the war the Fourteenth Amendment to the Federal Constitution was adopted, which prohibited the States from depriving any person of life, liberty, or property without due process of law, and from denying to any one the equal protection of the law. It was claimed by many that this operated to prevent the grant by a State of any special privileges, but in the Slaughter House Cases, 16 Wall. 36 (1872), a charter given by the State of Louisiana, which secured to the corporation a monopoly of the butchering business within certain limits of New Orleans, was held to be valid, and thus the right of each State to determine for itself, in the grant of privileges, that which was best for its citizens, was sustained. In 1890 came Leisy *v.* Hardin, 135 U. S., 100, in which it was held that the grant by the Federal Constitution to Congress of the power to regulate commerce between the States invalidated the legislation of one State which sought to prevent a citizen of another from selling and shipping liquors into it. In 1895, in the Income Tax Cases, 82 U. S., 429, it was held that the constitutional provision requiring direct taxes to be apportioned among the States according to their population rendered invalid a tax which was not so apportioned on incomes derived from real estate and as the direct product of personal property. And only recently were decided the Insular Cases, 128 U. S., 1, cases arising out of the conquest of Porto Rico and the Philippines, in which was considered the power of Congress to govern territories acquired by war or treaty, and in which was affirmed to the largest extent the national power of the Republic. This list might be greatly increased, but enough have been cited to show the general character of the cases considered and determined by that court in upholding the idea of nationality. It has always strongly upheld the powers given by the Constitution to the nation, and at the same time protected the States in the powers reserved by that instrument to them.

At first the amount of business in the Supreme Court was small; now it is large. In 1801, the first year of Chief Justice Marshall's term, only ten cases were filed; from 1875 to 1880 there were 1953, or an average of about 390 a year. While the act of 1891 diminished the number of cases that could come to the court, yet during the year 1900 401 cases were filed, and during the year 1901 383.

As heretofore stated, the court at first consisted of six members; it never has had at any time over ten, and now has but nine. The following is a list of the Chief Justices and also of the associate justices, as well as the States from which they were appointed: Chief Justices—John Jay, New York; John Rutledge, South Carolina; Oliver Ellsworth, Connecticut; John Marshall, Virginia; Roger B. Taney, Maryland; Salmon P. Chase, Ohio; Morrison R. Waite, Ohio; Melville W. Fuller, Illinois. Associate Justices—William Cushing, Massachusetts; James Wilson, Pennsylvania; John Blair, Virginia; James Iredell, North Carolina; Thomas Johnson, Maryland; William Paterson, New Jersey; Samuel Chase, Maryland; Bushrod Washington, Virginia; Alfred Moore, North Carolina; William Johnson, South Carolina; Brockholst Livingston, New York; Thomas Todd, Kentucky; Joseph Story, Massachusetts; Gabriel Duval, Maryland; Smith Thompson, New York; Robert Trimble, Kentucky; John McLean, Ohio; Henry Baldwin, Pennsylvania; James M. Wayne, Georgia; Philip P. Barbour, Virginia; John Catron,

Tennessee; John McKinley, Alabama; Peter V. Daniel, Virginia; Samuel Nelson, New York; Levi Woodbury, New Hampshire; Robert C. Grier, Pennsylvania; Benjamin R. Curtis, Massachusetts; John A. Campbell, Alabama; Nathan Clifford, Maine; Noah H. Swayne, Ohio; Samuel F. Miller, Iowa; David Davis, Illinois; Stephen J. Field, California; William Strong, Pennsylvania; Joseph P. Bradley, New Jersey; Ward Hunt, New York; John M. Harlan, Kentucky; William B. Woods, Georgia; Stanley Matthews, Ohio; Horace Gray, Massachusetts; Samuel Blatchford, New York; Lucius Q. C. Lamar, Mississippi; David J. Brewer, Kansas; Henry B. Brown, Michigan; George Shiras, Jr., Pennsylvania; Howell E. Jackson, Tennessee; Edward D. White, Louisiana; Rufus W. Peckham, New York; Joseph McKenna, California; Oliver W. Holmes, Massachusetts; William R. Day, Ohio. They hold office for life, and yet up to 1903 the average term of office of the Chief Justices had been 13 5-12 years, and of the associates 15 9-12 years.

That the work of the court has not only developed a national idea, but also has done much to give stability to republican institutions, is now conceded by all. See CONSTITUTION OF THE UNITED STATES; COURT; FEDERAL GOVERNMENT. Consult Curtis, *Jurisdiction of the United States Courts.*

SURABAYA, sōō'rä-bä'yȧ. The most populous residency in Java. Area, 2091 square miles. The soil is fertile and produces an abundance of rice, coffee, sugar-cane, indigo, and tobacco. Capital, Surabaya. Population, in 1897, 2,217,120.

SURABAYA, or **SOERABAYA.** The largest city in Java, and the capital of the Residency of Surabaya, situated in the eastern part of the north coast, at the mouth of the Kediri River, two days by rail from Batavia; latitude 7°12′ S., longitude 112°34′ E. (Map: East India Islands, D 6). It has regular steam communication with the other cities in the island and archipelago. It has a good harbor and strong fortifications and is the military and naval headquarters of the Dutch East Indies. The houses are generally separated by gardens. Simpang, the suburb, contains the home of the resident and a large hospital. The shipbuilding industry is important. The trade in rice, coffee, cotton, sugar, tobacco, and cocoanuts is very extensive. Population, in 1897, 142,080, of whom 6988 were Europeans, 121,075 natives, and 12,133 Chinese.

SURAKARTA, sōō'rä-kär'tȧ. A residency in the central part of Java, between Samarang and Surabaya. Area, 2404 square miles. The residency is one of the so-called independent States, and is governed by a native 'emperor,' who is subsidized by the Dutch and wholly under their control. Capital, Surakarta. Population, in 1897, 1,226,368.

SURAKARTA, or **SOERAKARTA.** The capital of the Residency of Surakarta, Java, on the left bank of the Solo River and on the railway between Samarang and Surabaya (Map: East India Islands, D 6). It is the residence of the native prince, whose palace is directly opposite the great fort called Vastenburg in the middle of the city. Population, in 1897, 86,074.

SURAT, sōō-rät'. The capital of a district of the same name, Bombay, British India, 150 miles by rail north of Bombay and about 15 miles from its port, Swalli, at the mouth of the Tapti, in the Gulf of Cambay (Map: India, B 4). The town is surrounded on the landward side by a brick wall. It has numerous mosques and several Hindu and Parsi temples and the palace of the former Nawab of Surat. The Tapti, owing to a sand-bar, affords entry only to small vessels, and the commerce of Surat, which from the sixteenth century to the eighteenth century was very extensive, has been steadily diverted to Bombay. Surat is a place of military importance, with a castle dating from 1540, centrally situated on the river front, and a cantonment, the residence of a British military commandant and other dignitaries. Surat rose into importance as the spot whence the Mohammedans of Hindustan embarked on their pilgrimage to Mecca. In 1612 the English East India Company established a factory here, which for some time was their principal trading station in India. In 1759 the castle was made over to the English and in 1800 they assumed the administration of the town. Population, in 1901, 118,364.

SURBITON. A town in Surrey, England, on the Thames, one mile south of Kingston, with which its industries are identified. Surbiton Common witnessed the last stand of the Royalists in the Civil War. Population, in 1891, 12,178; in 1901, 15,019.

SURDS. See IRRATIONAL NUMBERS.

SURESNES, sụ'rân'. A town of the Department of Seine, France, at the foot of Mont Valérien, on the left bank of the Seine, seven and a half miles west of Paris (Map: France, B 6). In 1593 a conference was held here which resulted in the adoption of Catholicism by Henry IV. Population, in 1901, 11,225.

SURETTE, sōō-rĕt', THOMAS WHITNEY (1862—). An American organist and composer. He was born in Concord, Mass., and studied music under Arthur Foote and J. K. Paine. In 1883 he became organist in his native town, and in 1894-96 was organist and choirmaster of Christ Church, Baltimore. In 1896 he became interested in the University Extension movement, and devoted most of his time to lecturing under its auspices on musical subjects. He also lectured on music at the University of the State of New York, Albany; at Oxford University, England; and at Mill Hill Abbey, London. As a composer he became known by his operetta *Priscilla* (1899), which has been frequently performed. In the same year he produced in Pittsburg a romantic opera named *Cascabel*, and also set Keats's *Eve of Saint Agnes* as a dramatic ballad.

SURETYSHIP (from *surety*, from OF. *surete*, *seurte*, Fr. *sûreté*, from Lat. *securitas*, freedom from care, from *securus*, free from care, from *se-*, apart + *cura*, care, anxiety). The engagement by which one person becomes legally bound to another for the liability of a third. It therefore involves three parties: the creditor, the principal debtor, and the surety. The distinction between this term and another which is often used interchangeably with it has been pointed out under GUARANTY (q.v.), and need not be repeated here.

It is generally held that surety agreements are subject to the ordinary rule of interpretation that a written contract is to be construed strong-

ly against the party executing it. This will always be enforced when it appears that the language was chosen by the signer, whether he enters into the contract for his own benefit or for the benefit of a third person. Another important rule is that such contracts shall be interpreted so as to give effect to all of their provisions if possible.

After the contract is made it is the duty of the creditor not to enter into any binding engagement with the principal, modifying that contract, without the assent of the surety. The law favors the surety and protects him with much jealousy. Accordingly, if the creditor varies the terms of the original contract or changes securities put into his hands by the principal debtor, or discharges a co-surety, or gives time to the principal debtor, or negligently causes a loss to the surety, the latter will be discharged unless he has assented to this conduct of the creditor. If, however, the principal debtor or a co-surety is discharged from liability by operation of law, as by a discharge in bankruptcy, the surety still remains bound.

The rights of the surety may be considered under three heads. First: Against the principal debtor. As soon as the debt becomes due, the surety is entitled to call on him for exoneration. This relief is obtainable in a court having equitable powers, it being unreasonable that the surety should have such a cloud hanging over him. If the surety has been compelled by the creditor to pay the debt he is entitled to call on the principal for reimbursement; for the money paid by him was paid for the principal's use. Second: Against the creditor. As soon as the debt becomes due the surety may compel the creditor to sue the principal and collect the debt from him. In some of our States the surety is discharged from liability if the creditor does not sue the principal upon the surety's request. One who is surety for the honesty or good conduct of an employee is entitled to have the employee discharged from service for serious defaults or breaches of duty, or to be freed from his suretyship. Another and very important right of the surety is to have the benefit of all securities which the creditor holds against the principal. This is known as the right of subrogation (q.v.). Third: Against co-sureties. It often happens that one surety is compelled by the creditor to pay the whole debt, and that the debtor is worthless. In such a case the unlucky surety is entitled to call upon his co-sureties for contribution. See SUBROGATION. Consult authorities cited under GUARANTY.

SURFACE (OF., Fr. *surface*, from Lat. *superficies*, upper side, surface, from *super*, above + *facies*, form, figure, face). The boundary between two portions of space. As a point in a plane is determined in general by two intersecting lines, so a point in space is in general determined by three intersecting surfaces. These surfaces may be plane, quadric, or of higher order according as their equations are of the first, second, or higher degree in the linear coördinates of the system. Thus in Cartesian coördinates (see COÖRDINATES) the general equation of the first degree in x, y, z, or $ax + by + cz + d = 0$, is represented by a *plane*. The general equation of the second degree in x, y, z, or $ax^2 + by^2 + cz^2 + 2fyz + 2gzx + 2hxy + 2kx + 2my + 2nz + d = 0$, is represented by a conoid, or surface of the second order, also called a *quadric* surface. By a suitable transformation of coördinates the general equation of the second degree may be transformed into one or the other of the forms (1) $Ax^2 + By^2 + Cz^2 = D$ or (2) $Ax^2 + By^2 = Cz$. Surfaces having the symmetric equation (1) are symmetric with respect to the origin as a centre and are called *central* quadrics. Non-central quadrics are included in equation (2). If $A = B = C$, equation (1) takes the form $x^2 + y^2 + z^2 = K$ $(= r^2)$, the equation of the sphere (q.v.). The general equation (1) represents either an ellipsoid (q.v.) or an hyperboloid. If $D = 0$, and A, B, C are not all positive, equation (1) represents a conical surface whose vertex is at the origin. Equation (2) is represented by the surface of a paraboloid (q.v.).

A surface through every point of which a straight line may be drawn so as to lie entirely in the surface is called a *ruled* surface. Any one of these lines which lies on the surface is called a generating line of the surface. The cylinder, cone, hyperboloid of one sheet, conoid (q.v.), and the hyperbolic paraboloid (see PARABOLOID) are ruled surfaces. There are two distinct classes of ruled surfaces, those on which the consecutive generators intersect and those on which they do not. The former are called *developable* and the latter *skew surfaces*.

If the degree of the equation $f(x, y, z) = 0$ is higher than the second, the surface representing it will be of an order higher than the second. In discussing the properties of such surfaces, especially the nature of the surface in the vicinity of any given point, the equation of the tangent plane at that point is necessary. This plane is the locus of all tangent lines through the given point, and will meet the surface of the nth order in a curve of the nth degree, since each straight line meets this curve in n points. The point of contact of the plane with the surface will be a singular point on the curve. (See CURVE.) The section of any surface by a plane parallel and indefinitely near to the tangent plane at any point is a conic and is called the *indicatrix* at the point. Thus points of a surface are called elliptic, parabolic, or hyperbolic, according as the indicatrix is an ellipse, parabola, or hyperbola. If every straight line through a point (x', y', z') of a surface meets the surface in two coincident points, the point (x', y', z') is called a *singular* point. If the tangent lines at any point form a cone the point is called a *conical* point; if they form two planes the point is called a *nodal* point. Similar to the envelope of a family of curves, the envelope of a family of surfaces is the locus of the ultimate intersections of a series of surfaces produced by varying one or more parameters (q.v.) of an equation. The curve in which any surface is met by the consecutive surface is called the *characteristic* of the envelope. Every characteristic will meet the next in one or more points, and the locus of these is called the *edge of regression* or cuspidal edge of the envelope. The conditions for convexity and concavity, different orders of contact, and various other properties are best obtained from works on analytic geometry.

SURFACE, JOSEPH. A sentimental, plausible hypocrite in Sheridan's *School for Scandal*, Charles's elder brother, who pursued Maria for her fortune.

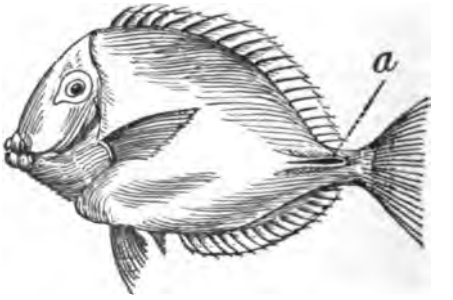
SURFACE TENSION. See CAPILLARITY.

SURF-BIRD. A remarkable plover-like bird (*Aphriza virgata*) widely distributed on the coasts and islands of the Pacific Ocean, and common along the entire west coast of North America. It is about nine and a half inches long, dark ashy brown above, white beneath, everywhere more or less spotted, streaked, or barred with black. The feet are like those of a sandpiper, but the bill is plover-like, short and thick. The wings are very long and acute, reaching beyond the end of the tail when folded. It is clearly related to the turnstone (q.v.).

SURF DUCK, or SURF SCOTER. See SCOTER.

SURF-FISH. A fish of the suborder Halconoti and family Embiotocidæ, related to the percoids. Many species occur on the Pacific Coast

A SURF-FISH, THE ALFIONA.



of the United States, where they inhabit bays and the surf on sandy beaches. They are small, oval-oblong, compressed, and often very handsome, with stripes, spots, and effusions of various colors. Their flesh is not very highly regarded. The fact of greatest interest connected with them is that they are viviparous. One of the largest and most useful of the family is the 'alfiona' (*Rhacochilus toxotes*).

SURF SMELT. A small, firm-fleshed, and fat smelt (*Hypomesus pretiosus*) of the coast of California and northward, valued as food. It spawns in the surf, and is netted in great quantities. See Plate of WHITEFISH, SMELTS, ETC.

SURGEON, MILITARY AND NAVAL. Appointments to the medical corps of the United States army or navy are made by the President of the United States upon recommendation of candidates by the surgeons-general of the army and navy, and after satisfactorily passing the examinations of the respective medical examining boards. Candidates for the army medical service must be between the ages of twenty-two and twenty-nine years; for the navy, between the ages of twenty-one and thirty. A candidate for either service must be a graduate of a regular medical school. Appointees are admitted to the service of the army and navy as assistant surgeons, with the rank of first lieutenant in the army and lieutenant (junior grade) in the navy. A surgeon in the army has the rank of major, and is required to have been an assistant surgeon at least five years. A surgeon in the navy has the rank of lieutenant and must have been an assistant surgeon for two years. Prior to regular assignment, United States army surgeons go through a five months' course at the Army Medical Museum, Washington, D. C.

The Royal Army Medical Corps of Great Britain differs from the United States in that it is a distinct branch of the service; the surgeons and enlisted men use the same distinguishing titles of rank as the combatant arms, and the officers prefix the word surgeon before the rank. They are under their own headquarters organization, and are rarely, even indirectly, subject to the authority of commanding officers of other branches. Members of the corps are armed and trained for military as well as medical emergencies. The Sanitary Corps of Germany and France are on similar lines to the United States, differing principally in the details due to general army organization. See SURGERY, MILITARY; ARMY ORGANIZATION; HOSPITAL; HOSPITAL CORPS.

SURGEON-FISH (so called from the lancet-shaped spine), or SEA-SURGEON. One of a family (Teuthididæ) of tropical Oriental fishes, of which about 80 species are recognized, and which feed upon seaweeds. Those best known are of the genus Teuthis, called 'barberos,' 'lancet-fishes,'

SURGEON-FISH.
a, position of the lancet and its sheath.

'tangs,' and so on, and characterized by the possession of a long, sharp, lancet-like spine on each side of the caudal peduncle. The spine is movable and shuts into a groove along the side of the tail.

SURGERY (OF. *cirurgerie, cirurgie, sirurgie*, Fr. *chirurgie*, surgery, from OF. *cirurgien, serurgien*, Fr. *chirurgien*, surgeon, from Lat. *chirurgus*, from Gk. χειρουργός, *cheirourgos*, surgeon, handicraftsman, from χείρ, *cheir*, hand + ἔργον, *ergon*, work). In contradistinction to medicine surgery embraces a consideration of those disease conditions that are treated chiefly by mechanical methods rather than by the administration of drugs. This classification is naturally arbitrary; and now that the dangers of surgical operations have so materially diminished, diseases formerly looked upon as hopeless or as suitable for medical treatment only are included among the surgical affections. It is

incorrect, however, to assume that surgery consists entirely or even in great part in the elaboration of methods of treatment; the pathological processes so treated demand and receive their proper degree of investigation and study.

Up to the time of Hunter (1728-93) surgery, and indeed medicine, were based in their practice almost entirely upon tradition and dogma. Hunter, by his labors in the direction of anatomy and physiology, lifted medicine from the obscurity of philosophical doctrine to the firm foundation of facts and imparted an impulse that is still felt and is still in evidence in the methods of research employed to-day in the fields of comparative pathology and experimental medicine which promise most for the advancement of the medical and allied sciences. With Hunter's death, however, ended the active prosecution of original investigation; and although the high position of English surgery at that time was preserved by the clinical and other work of Hunter's successors, notable among whom are Charles Bell, Astley Cooper, Abernethy, and Jenner, the laboratory methods employed by him were largely abandoned and have only within relatively few years been revived. From Hunter's period to the introduction of anæsthesia there is no remarkable fact in the development of surgery. During this time the efforts of surgeons seem to have been directed chiefly to the perfection of the bedside methods and the influence of the profession in America began to make itself felt. Ephraim McDowell, a native of Kentucky and trained under Bell in Scotland, in 1809 first successfully opened the abdominal cavity and removed an ovarian cyst, thus establishing forever one of the most beneficial of operations. A little later Valentine Mott of New York successfully applied ligatures to some of the largest arteries, for the relief of aneurism, and demonstrated the curability of this disease in positions in which it had previously been invariably fatal. The introduction of general anæsthesia (q.v.) in 1846 by Warren in the Massachusetts General Hospital marks the greatest stride in the progress of surgery up to that time. This property of ether was discovered independently by Long of Georgia and Morton of Boston, but it remained for Warren to popularize it by making use of it publicly, repeatedly and with success. A year later Simpson of Edinburgh introduced chloroform. The propulsion to the practice of surgery given by the employment of general anæsthesia during operations can hardly be exaggerated. Before that time operative treatment of disease was limited in its application to lesions correctible by coarse methods and in briefest time. Human beings, surgeons and patients, could not endure the pain of protracted operations, nor could sufficient freedom from struggling be secured to make refined dissections possible. Under the influence of anæsthesia quiet was obtained and the necessity for great speed was greatly diminished, so that new operations were soon planned, new regions invaded, and detailed procedures devised and new and better results achieved. Even after the introduction of anæsthesia, however, operations and all injuries continued to be looked upon with for they were almost invariably followed or the other of the infectious wound and deaths from septicæmia, pyæmia, hospital gangrene, etc., were so common

mortality after even trifling operations was not small.

Pasteur then began the series of observations and experiments that finally enabled him to indicate the causes first of fermentation and then of wound diseases, and to identify some of the agents as members of the class of beings known collectively as bacteria. Lister seized these facts and applied them in surgery. His notion was that the infectious wound diseases were due to the deposit upon the raw surface exposed in open injuries of the bacteria floating in the air, and he therefore aimed at the sterilization of the air in the neighborhood of wounds during the course of operations, and at the exclusion of air from wounds during healing. The first was attempted by saturating the air in contact with wound surfaces with the vapor of carbolic acid, and from time to time flooding wounds with solutions of the same substance or of corrosive sublimate; the second object was accomplished by covering wounds during repair with dressings impregnated with the same antiseptics.

The effect was apparent at once in the results of operations, in lowered mortality, and in recoveries with fewer complications. This plan of treatment, properly called antiseptic, was found, however, to possess serious dangers to both surgeon and patient in the risk of poisoning by the powerful germicides necessarily employed, and the idea began to develop that it was more logical to prevent the inoculation of wounds by bacteria from any source than to attempt their destruction after they had gained entrance. Meanwhile the rapid growth of the science of bacteriology had reached a development that led to the identification of the bacteria causing the common wound diseases and had made surgeons familiar with their distribution, the modes of growth within and outside of the body, and the means of destroying them. The adoption of methods of conducting operations and treating wounds whose purpose was absolutely to prevent the inoculation of denuded surfaces and tissues by bacteria followed naturally, and now has become universal; and the methods have become so perfect that wound diseases due to bacteria are rare except after accidental injuries, and some of the most serious of them have virtually ceased to exist. Few men of the present generation of surgeons have seen hospital gangrene, for example, a disease which has been the cause of thousands of deaths.

The possibilities suggested by the relative freedom from danger with which operations were carried out were quickly appreciated by the medical profession, and the cure of disease by operative measures was soon extended to regions in which, previously, operations had been undertaken with the greatest misgiving, or not at all. In consequence, to-day the surgeon opens the cranial and spinal cavities, the thorax, the abdomen, and the joints with perfect confidence that no ill will result from the operation itself; and the benefits that have thus been secured in the relief of lesions of the viscera contained in these cavities cannot be adequately estimated. While the attention of the surgeons during the last two or three decades has been in great part directed toward the perfection of operative technique, progress in other lines has also gone on, and during this period the knowledge of the pathology of many surgical affections has been great-

ly widened, with corresponding refinements in their treatment.

Not the least important factor in the great progress which has been made in surgery and in medicine also is the method by which the subject is now taught, and the candidate for the degree of doctor in medicine is now qualified to undertake the management of the cases he may be called upon to treat. Up to twenty years ago the instruction to medical students consisted very largely of didactic lectures on the various branches of medicine, supplemented by clinics at which various diseases were demonstrated and their treatment indicated or carried out by the professors. The student but rarely came into contact with the patient. With the better appreciation of the value of laboratory methods of instruction in the natural sciences which were originally adopted by Hunter and revived and insisted upon by Huxley, they began to be utilized in medical schools, and were gradually elaborated until at present in almost every department the student gains his information and experience in that way. The result is that didactic lectures have been greatly diminished in numbers. During the first year of instruction the medical student is introduced in this way to normal human anatomy and physiology; in the laboratories he studies the gross and minute structure of the body and the functions of the tissues of which it is composed. During the second year he is taught by the same means the general process of deviation from the normal that constitutes disease. During the third year he studies specific instances of deviations from the normal and learns to identify them as particular diseases. At this time he is brought into contact with patients suffering with the diseases with which he has more or less familiarized himself in the laboratory and concerning whose causation and pathology he is fully informed, but whose symptoms and treatments he has yet to learn. The laboratory method is still pursued, but the dispensary and the hospital have now become for the student his laboratory, and it is in them during his fourth year that he spends the major part of his time. Thus up to the point of gaining experience in performing operations the student is as well instructed as he can well be. This field is well covered by the performance of operations upon the cadaver where practically all of the major and minor operations can be as well practiced as upon the living; and for special purposes operations can be carried out upon the dog.

As time has progressed and the treatment of diseases peculiar to particular regions has become more refined, special divisions of surgery have naturally arisen; and this specialization has contributed in no small degree to the rapidity of the development of surgery. There are now the well-recognized departments of ophthalmology, treating of diseases of the eye; otology, treating of diseases of the ear; rhinology and laryngology, treating of diseases of the nose, throat, and larynx; gynecology, treating of diseases of the female; genito-urinary surgery, treating of the diseases of the male; dermatology, treating of diseases of the skin; orthopædic surgery, treating of deformities growing out of diseases of the bones and joints. In the case of all of these specialties the feature that makes them departments of surgery is the fact that the diseases peculiar to each are treated by mechanical means, either by the application of fixed apparatus to be continually worn through long periods or by bloody or non-bloody procedures whose duration is brief.

Operations. The purpose in view in designing operations is very variable and scarcely admits of formulation with any accuracy. They may be planned in case of injuries to close superficial or deep-seated wounds, to stop bleeding, to facilitate the adjustment of broken bones or the reduction of dislocated joints, to remove foreign bodies, or to make disinfection and drainage easier. In inflammations operations may be required to evacuate pus, to establish drainage, or to remove inflammatory tissue. In case of tumors, operations are done for their removal. In deformities, operations may be required to restore the normal contour of the region. In the contemplation of a typical operation to be performed under average circumstances several factors necessarily come up for consideration in detail: (1) The operating room, instruments, dressings. (2) Preparation of the patient. (3) Preparation of the surgeons. (4) The operation. (5) After-treatment.

(1) *The Operating Room.*—This should be of good size, well lighted, and of a temperature of between 70° and 80° F. All furniture, carpets, and hangings should be removed, the walls and ceiling rubbed over with moist bread crumbs, and the floor scrubbed. The operating table should be made especially for the purpose. On each side of the table and at its head there should be one or two small tables, those on the operator's side for the instrument trays, those on the assistant's side for the sponges, towels, dressings, etc., and that at the head for the anæsthetics, stimulants, etc. On each side of the table there should be a large basin in which the hands of the operator and his assistant may be rinsed from time to time. The *instruments* vary with the character of the operation to be performed. They should be made entirely of metal to withstand the heating necessary for sterilization, and as smooth as possible to avoid lodgment for bacteria. They are sterilized immediately before use by boiling for fifteen minutes in a 1 per cent. solution of sodium carbonate, and are then transferred to trays themselves sterilized by thorough washing in 0.2 per cent. solution of bichloride of mercury and lined by sterile towels. The *suture and ligature materials* are also sterilized, silk by being exposed to steam at about 250° F. for one hour, catgut by boiling in absolute alcohol under pressure for one hour. *Dressings* composed of absorbent material (usually cheese-cloth and cotton) and the pledgets of gauze with which the wound is kept free from blood during the progress of the operation are sterilized by being exposed to steam at 250° for one hour. The *basins, trays, and other receptacles* used during operations are sterilized by prolonged submersion in strong (0.2 per cent.) solutions of corrosive sublimate. The *solutions* used are 0.1 per cent. bichloride of mercury for the hands and towels; for douching wounds 0.6 per cent. solutions of sodium chloride are employed, sterilized by being boiled in cotton-plugged flasks for one hour on two occasions.

(2) *Preparation of the Patient.*—Twenty-four hours before operation the skin at the site

chosen for incision and for a wide area around it is thoroughly scrubbed and shaven and then covered by a soap poultice. Immediately before the operation the skin is again scrubbed, wiped off with spirits of turpentine, ether, and a 0.1 per cent. solution of corrosive sublimate in alcohol. If local anæsthesia is sufficient it is secured by the injection into the skin and subcutaneous tissues of dilute solutions of cocaine. If general anæsthesia is necessary, ether, chloroform, or nitrous oxide may be used, the choice depending upon the duration of the operation and upon the presence or absence of certain physical changes in the heart, blood-vessels, lungs, and kidneys. In any case the necessary restoratives must be at hand.

(3) *The Surgeons' Preparations.*—The surgeons' preparations consist in sterilization of their hands and forearms and in the assumption of gowns designed to prevent dust from settling from the clothing upon the wound, instruments, etc. Such gowns are of coarse cotton or linen, and extend from the neck to the feet; the sleeves only reach the elbow. They are sterilized by steam before using. The hands and forearms of all persons likely to handle the wound, instruments, dressings, etc., are thoroughly disinfected and the hands covered by thin rubber gloves previously sterilized by boiling.

(4) *The Operation.*—In addition to the procedures necessary to fulfill the purpose of the operation, the most painstaking care is exercised to exclude all bacteria from wounds, in aseptic operations; and to kill or remove the bacteria present, and to avoid the introduction of more bacteria, in antiseptic operations. Therefore, besides the elaborate preparations just described during the progress of an aseptic operation, much attention must be paid to cleanliness. (a) No substance—finger, instrument, sponge, or dressing—is allowed to come into contact with the wound unless previously sterilized. (b) Instruments, sponges, and the surgeons' and assistants' hands are rinsed in sterile solutions from time to time. (c) If, for any reason, hands or instruments become soiled, they must be resterilized before again coming into contact with the wound. (d) No antiseptic fluids are to be used in the wound. If any flushing at all is necessary, sterile salt solution only is allowable. For antiseptic operations, the same preparations are made, but here it is often advisable to use antiseptic rather than simple sterile solutions. Otherwise the precautions are the same.

The first step in so-called bloody operations is the division of the integument. This is done by cutting implements, as knives and scissors, or, sometimes, by the actual cautery, or the écraseur. Subsequent steps are accomplished in a variety of ways: To expose deep-seated tissues, retractors are used. To facilitate dissection, various forms of forceps are used. To puncture cavities, hollow needles and trocars are used. To scrape out tissue, sharp spoons are used. To divide bones, saws, chisels, and strong cutting forceps are used. The division of tissue involves more or less bleeding. To prevent bleeding, in operations upon the extremities digital or instrumental compression of the afferent arteries is practiced, or the afferent artery may be ligated as a preliminary step. During the progress of the operation the 'bleeding points'—ends of the vessels—are seized by clamps, and then ligated with catgut. General oozing is controlled by packing the wound with dry gauze, or by flushing it with very hot salt solution, or by touching the surface with the actual cautery, or by elevating the part. At the end of the operation it remains to treat the wound so as to secure healing in the shortest possible time, and with a minimum scar, i.e. to secure union by first intention. For this purpose every obstacle to such union is removed. (a) Bleeding is absolutely stopped. (b) Foreign bodies, including bacteria, are removed. (c) The walls of the wound are brought into close contact and no 'dead spaces' allowed to remain. (d) Drainage is provided for, i.e. vents established for the escape of wound secretions. (e) The wound is protected from possible bacterial invasion, and the wounded tissues supported and immobilized by dressings.

(5) *After-Treatment.*—After the dressing has been applied, the patient is moved to his bed and allowed to recover from the anæsthetic. Morphine is often given to diminish vomiting and to mitigate anticipated pain. General symptoms, as shock or acute anæmia, are treated if they exist. No food or drink is given by the mouth until the nausea and vomiting caused by the anæsthetic have ceased. Then small but increasing quantities of milk or beef-juice are given until the desired diet is taken. If there is retention of urine, the bladder is emptied with the catheter. The bowels are to be moved by the second or third day after operation. Drains are removed in two to five days. Sutures are removed in five to seven days. If suppuration, due of course to bacteria, develops, the particular inflammation excited is to be treated as indicated by its characteristics.

From what has just been outlined it is obvious enough that all of the conditions looking toward the successful issue of a serious operation can be secured only in hospitals of first-class equipment; and it is to be noted that this fact is becoming so generally known that hospitals of the first class are being established and operated not only in the larger cities of this country, but also in the smaller ones and even in villages. Institutions of this kind are of benefit to the communities in which they exist and by which they are supported in many ways. They furnish at a nominal cost, or very often without charge, care for the sick poor that could be supplied in no other way; and the well-to-do may find in them facilities for the treatment of disease and particularly for the conduct of operations that cannot be secured even in their own homes. For the community at large they are also of the greatest value, since they afford for the medical men who serve in the hospitals a field which amplifies their experience indefinitely. Again, in the larger cities where medicine is taught as before outlined the hospitals may be regarded as parts of the laboratory system. The wards are the places in which the student finally gains his practical experience in the recognition of particular disease forms and the treatment of them.

SURGERY, Military. The best civil have proved the best military surgeons, as is shown by the great names in surgical history, Ambroise Paré, Larrey, Pirogoff, Von Bergman, Von Esmarch, Billroth, and Lister. Not until the discovery of asepsis and antisepsis was the true foundation laid for the modern treatment of gunshot wounds. This discovery so radically changed

all former methods of treatment as to lead to the now thoroughly established maxim formulated by Senn in the recent war between the United States and Spain, "The fate of the wounded rests in the hands of the one who applies the first dressing." The lesson has only recently been learned that bullet wounds must never be touched on the field—much less explored by probing or otherwise—before the first aid (antiseptic) dressing is applied. Operative interference is justifiable on the battlefield only in cases of extreme urgency, where extensive hemorrhage exists, or where the wound is in the region of the throat and suffocation is imminent. As a rule gunshot wounds are bloodless. Primary hemorrhage, unless resulting from the very rare accident of cutting some large vessel, is usually absent altogether, or can readily be controlled by a compress or first aid bandage. Especially in wounds of the abdomen the law of non-interference applies with double force. In the Spanish-American War 50 per cent. of all the cases of abdominal wounds unoperated upon recovered, while all operated upon died. In the Russo-Turkish War, that great apostle of conservatism in military surgery, Von Bergman, by the use of occlusive dressings, immobilization of the limb, and antiseptic precautions, saved thirteen out of fourteen cases of severe gunshot wounds of the knee-joint complicated with extensive comminution of the bone, while of similar cases treated by the old method of exploration without antiseptic precaution 95 per cent. died.

Observations during the recent Spanish-American War and the Boer War have led to the following deductions: (1) Small-calibre bullet wounds are usually aseptic and heal promptly. (2) Jagged and extensive wounds, poisoned by such missiles, are due to the detachment of the jacket, the introduction into the bullet of foreign particles (such as cloth, buttons, etc.), lateral impingement of the bullet, or ricochet. (3) Owing to the small diameter of the bullet and its great velocity, the orifices at entrance and exit are minute, and it is almost impossible to distinguish one from the other. (4) The cardinal principle has been established that manipulation of such wounds and probing on the field (except in the rarest instances) is surgical malpractice.

To Esmarch is really due the latest conception of the axiom '*laissez aller*,' and his first aid package is a memorial to his practical grasp of the principles of wound infection. The first aid package has been modified by Senn, of Chicago, who emphasizes his conclusions as follows: (1) First aid packages are indispensable on the battlefield in modern warfare. (2) The first aid dressing must be sufficiently compact and light to be carried in the skirt of the uniform, or on the inner surface of the cartridge or sword belt, to be of no inconvenience to the soldier or in conflict with military regulations. (3) The Esmarch triangular bandage is of great value in the school of instruction, but as a component part of the first aid package it is inferior to the gauze bandage. (4) The first aid package must contain in a waxed aseptic envelope an antiseptic powder, such as boro-salicylic powder; two strips of aseptic lintine, each $2\frac{1}{2} \times 4$ inches; a triangular piece of gauze, the diagonal half of a square yard; sterilized pins wrapped in tin foil, and between this package and the outside impermeable cover, two strips of adhesive plaster an inch wide and eight inches long. (5) The first aid dressing must be applied as soon as possible after the receipt of the injury, a part of the field service which can be safely intrusted to competent hospital corps men. (6) The first aid dressing, if employed on the firing line, should be applied without removal of the clothing over the injured part, and fastened to the surface of the skin with strips of rubber adhesive plaster, the bandage being applied over and not under the clothing. (7) The first aid dressing must be dry and should remain so by dispensing with an impermeable cover of any kind over it, so as not to interfere with free evaporation of the wound secretion. (8) The first aid dressing should not be disturbed unnecessarily, but any defects should be corrected at the first dressing station.

Suppurating wounds from small-calibre bullets, having high velocity, heal with comparative promptness. Wounds from such bullets are necessarily more humane and less painful than those from the older missiles; but the relative percentage of deaths to wounded is but slightly reduced. Unless unusual complications call for immediate surgical interference, the injured should be removed as rapidly as possible to a well-equipped base or general hospital for treatment. Penetrating abdominal and thoracic wounds give a vastly larger percentage of recoveries where non-interference has been observed. Laparotomy, except under the most favorable conditions, such as hold in well-equipped hospitals, is attended with great peril. The Röntgen ray has been of utility in indicating where surgical interference is justified and in many cases has averted infection which would result from probing or similar surgical procedures. It has also thrown light on the pathology of wounds involving the solid structures, and shown that the severest lesions of bones will progress toward recovery, provided the wound is sterile. It proved an invaluable aid in the Spanish-American War, in the Boer War, and in the Philippines, where it was used in general hospitals at the base of operations and on hospital ships; but it is not a practical apparatus near the firing line, where its use in the detection of bullets could only prove an incentive to premature operations. The modern jacketed bullet is practically aseptic; there is never urgency for its removal except where aseptic technique is possible, otherwise infection of the wound is an inevitable consequence. The Röntgen ray was also of especial scientific value in gunshot fractures by showing the character of the bone lesions, the form of the fracture, and the amount of bone comminution by small-calibre bullets, fragments of shells or other missiles, conditions that could not have been otherwise determined in the living body, thus also proving an important factor in developing the principle of conservatism in surgery of war.

It is to Pasteur and Lister that military surgery owes its greatest debt. They have simplified its labors and taught the great lesson of non-interference. The soldier who falls on the battlefield from the effect of a ball passing through any but a vital part of his anatomy and who has a 'first-aid' dressing promptly applied and is then transported to a general hospital where the Röntgen ray and the principles of asepsis and antisepsis can be utilized, has a far greater chance of recovery than when his wounds are treated on the field. By following these conserva-

tive methods in the Spanish-American War the percentage of recoveries was 95.1 per cent., while 4.9 per cent. died, a ratio never before attained in the history of warfare.

The medical corps of different armies vary little in their personnel. There is one surgeon-general; a chief surgeon to each separate army corps, division, brigade, and general hospital; a surgeon and two assistants to each regiment; and a single surgeon with each battery or separate detachment. These are all commissioned officers. The hospital corps comprises the hospital stewards and their assistants, privates often selected to serve as pharmacists, orderlies, nurses, cooks, litter-bearers, and ambulance-drivers, and should equal four per cent. of the fighting force of the army. In addition to a canteen, the United States Hospital Corps men carry a corps pouch and an orderly pouch. The corps pouch contains aromatic spirits of ammonia, first dressing packets, wire gauze for splints, gauze bandages, rubber bandages, surgical plaster, scissors, pins, forceps, and knife. The orderly pouch contains chloroform, antiseptic tablets, pocket case, ligatures, hypodermic syringe, etc. Medical and surgical chests used on the march or at the front should contain, as stated by Surgeon-General Forward, United States Army, "surgical material mainly, and very little medicine, which may be for the most part in tablet form. The principal articles are splints and modern wound dressings, including plaster rollers, and rubber plaster for rapid fixation of splints; a light complete operating set, tin trays, basins, and cups in nests; chloroform and inhaler; rubber tubing, needle, and canula; and pure sodic chlorid for transfusion; mercuric bichlorid, tricresol, iodoform, soda, and green soap; rubber bandage and rubber gloves; hypodermic syringe and full sets of tablets; purgative pills, quinine, and a few other medicines; concentrated food and stimulants; small case of 'tools in the handle,' and a lantern. The dressings consist mostly of bichlorid and iodoform gauze, absorbent cotton, and gauze bandages. They should be in small parcels, compressed, and wrapped in strong waterproof paper, to save waste and contamination, and for convenience in transportation, handling, and distribution."

The same general directions—relative to (1) the operating room, covering instruments and dressings; (2) preparation of the patient; (3) preparation of the surgeons; (4) the operation; and (5) after-treatment—that apply in general surgery (as stated in the article SURGERY) apply also to military surgery at the base hospitals, and successful results will follow in exact proportion as these details are carried out. It is not therefore to any special training in surgical technique that the military surgeon will owe his triumphs. History has shown that more campaigns have been decided by disease than by the sword. Statistics of wars for the past hundred years, while varying in some particulars, have concurred to establish the fact that for every soldier killed in battle there are five wounded who recover. The introduction of modern weapons with the compound metal-jacketed small-calibre balls of high velocity and great range, has shown no perceptible change in the proportion of these figures, viz. one killed to five wounded. It is also an established fact that for every man killed in action or who dies from the results of wounds, at least five die from disease that is almost invariably of a preventable character. In the American Civil War (1861-65) 110,070 were killed, and over 249,458 died from disease. These proportions were higher in the war of the Crimea and also in the Mexican War; and in the Spanish-American War, although actual hostilities only lasted for a period of six weeks, the proportion of losses by disease was even higher still.

When these appalling figures are properly recognized, and the advantages of extreme conservation on the field is appreciated, the true field of the military surgeon will be found. He must possess executive ability and a certain amount of military training, so that in time of action he can quickly organize his assistants and hospital corps, seeing that the wounded are brought promptly from the firing line to the first dressing station. This should be located at the nearest protected spot to the firing line. Here the wounded man can receive such immediate attention by the surgeon or an assistant as is imperatively demanded; dressings if out of place can be readjusted; in case of fractures or joint injuries the limb can be immobilized in splints, and the soldier can rest until transported by ambulance or otherwise to the field hospital, which should be located well in the rear. Here the case can receive thorough attention, and later be transported to a general or base hospital, a hospital ship, or a civil hospital, as is deemed most advisable. The problem of rapid transportation of the wounded is one that should engage much attention. Splendid results in the development of this feature were attained in the war with Spain, by the hospital ships and fast railway train in charge of the surgeons of the American Army, and many valuable lives were saved in consequence.

But it is at times when the army is not in action that the responsibilities of the military surgeon are greatest. In order to prevent the invasion of that deadlier foe, whose fatalities in every year are never less than five times greater than those killed in battle, he must prove himself a keen sanitary engineer in the selection of camp sites, of camp drainage, of the location of latrines; in the inspection of all water supplies, the quality of food and its cooking, and of the soldier's clothing and his personal cleanliness. He must be an epidemiologist and a bacteriologist, as well as a student of dietetics and metabolism. Terrible epidemics of typhoid fever, cholera, dysentery, and diarrhœa have resulted from flies carrying disease germs from unsavory places to the mess-hall, or through the drinking of polluted water. The parasite of malaria and of yellow fever is transmitted through the medium of the mosquito, that of tuberculosis through the sputum. (See INSECTS, PROPAGATION OF DISEASE BY). The iron-clad ration of the soldier has at times led to starvation or scurvy, or has proved an excitant to intestinal disease. With all these problems the military surgeon must be prepared to wrestle, especially when he is with newly recruited troops, unaccustomed to the rigorous discipline of army life, or when stationed in tropical climes. The normal condition of the soldier is health; disease and premature death are to a large extent unnecessary. "They are to be overcome, however, not by the abrogation of the intellectual faculty, but by its exercise."

SURGICAL ASSOCIATION, AMERICAN. A society founded in 1880 for the primary purpose of cultivating and improving the science and art of surgery. The active membership is limited to 125 fellows; the honorary membership to 25 fellows. An applicant to be eligible for fellowship must be thirty years old, a graduate of five years' standing from a recognized medical college, and have an established reputation as a practitioner, author, or investigator. The meetings of the association are held annually. Every third year the association joins with the constituent associations of the Congress of American Physicians and Surgeons in a meeting held in Washington, D. C. An annual volume of *Transactions* is published containing the papers presented at each meeting.

SURICATE. The meerkat (q.v.).

SURIGAO, sōō'rē-gä'ō. A province of Mindanao, Philippine Islands, occupying the northeastern portion of the island, and bounded on the west and south by the provinces of Misamis and Dávao (Map: Philippine Islands, K 11). Area, 13,201 square miles. The greater part is covered with forests, and the river forms almost the only means of communication, most of the towns being situated on its banks. Cotton, hemp, rice, sugar, and tobacco are raised, and betelnuts and cocoanuts are exported. Population, estimated in 1901, at 85,125, largely Visayans. Capital, Surigao (q.v.).

SURIGAO, STRAIT OF. The strait connecting the Sulu Sea with the Pacific Ocean, extending between the island of Mindanao on the south and the islands of Negros, Cebu, Bohol, Leyte, and Samar on the north (Map: Philippine Islands, K 10).

SURINAM, sōō'rē-näm'. A river of Dutch Guiana. It rises in the south central part of the country, and flows northward, emptying into the Atlantic Ocean through an estuary three miles wide, on whose shore lies the town of Paramaribo. Length, 400 miles. It is navigable 40 miles for the largest vessels, and 100 miles for ships drawing 10 feet. Near its mouth it is joined by the Cottica River, a navigable channel running 100 miles parallel with the coast and connecting with the mouth of the Maroni.

SURINAM. A Dutch colony in South America. See GUIANA.

SURINAM TOAD. See PIPA.

SURMULLET (OF., Fr. *surmulet*, from *sur, sor, saur*, reddish + *mulet*, diminutive of *mulle*, from Lat. *mullus*, red mullet). One of certain species of mullets found for the most part in the tropical seas. The striped red surmullet (*Mullus surmuletus*), attaining a weight of six to eight pounds, is sometimes abundant on the coasts of Europe. A very similar species (*Mullus auratus*), about eight inches long, occurs along our Atlantic coast, particularly toward the south. See Plate of MULLETS AND ALLIES.

SURNAME (OF., Fr. *surnom*, from ML. *supernomen*, surname, additional name, from Lat. *super*, above, over + *nomen*, name). In modern usage, the family name, as distinguished from the given or individual name. Many are based on personal peculiarities, as William Rufus, John Lackland, and are consequently originally mere epithets. Another class is patronymic, indicating of whom the person bearing the name is a son. Here belong the numerous names like Johnson, Thompson, Williamson. This form of surname prevailed especially in Scandinavian countries, and survived in Denmark until the middle of the nineteenth century, when it was replaced by the system of family names. A third class is given by the occupation or place of residence. Surnames were not generally used as family names until the thirteenth century. See COGNOMEN.

SURPLICE (OF., Fr. *surplis*, from ML. *superpelliceum*, surplice, from Lat. *super*, above, over + ML. *pellicia*, fur garment, *pelisse*, from Lat. *pelliceus*, made of skin, from *pellis*, skin). A linen vestment worn in the Roman Catholic Church by all ecclesiastics in choir except the officiants of the mass, and by the clergy of the Anglican communion; also, in both churches, by laymen and boys who sing in the choir or assist at the altar. The shape of the vestment in mediæval days was long and flowing; the modern tendency has been to reduce its size so that it usually comes little below the waist. The Italian name *cotta* is frequently applied to the modern vestment.

SURRENDER. In law, the giving up or abandonment of an estate for life or years in real property to the person next entitled to the remainder or reversion, with intent to merge the lesser estate in the greater. This differs from *renunciation* (q.v.), which is practically the refusal to receive an estate to which one is legally entitled. A valid surrender can only be made by an adult person of sound mind. Under the Statute of Frauds in most States, a surrender *in fact*, that is, by agreement, can only be made in writing. Thus, the mere cancellation or destruction of the instrument creating the estate will not operate *ipso facto* as a surrender. However, a surrender may take place by operation of law. Thus, where the landlord accepts another person as tenant; where the landlord takes possession of the premises to his own use; or where the tenant accepts a new lease for the same premises, these acts will be construed as a surrender by operation of law. The legal effect of a surrender is to terminate the relation of landlord and tenant, and to discharge the latter from liability for future rent, though not for rent already accrued. See LANDLORD AND TENANT, and authorities there referred to.

SURREY. A southeastern inland county of England, bounded on the north by Middlesex, and on the east by Kent (Map: England, F 5). Area, 758 square miles; population, in 1891, 1,731,343; in 1901, 2,008,923. The surface is hilly and diversified, with a northern slope toward the Thames. The principal streams are the Mole and Wey, tributaries of the Thames. The northern half of the county along the valley of the Thames is fertile and largely cultivated, hops, wheat, and the ordinary crops being raised; market gardening constitutes a lucrative industry. In the west and southwest the land is to a great extent covered with heath. The numerous manufactures include silk, cloth, leather, paper, pottery, and beer. Lambeth, Southwark, and other portions of southern metropolitan London are in the county, which is a favorite suburban residential section of London business men.

SURREY, HENRY HOWARD, Earl of (c.1517-47). An English soldier and poet, son of

Lord Thomas Howard, affirmed third Duke of Norfolk. His youth was spent in France, and at the Court of Henry VIII., and he received a careful classical education. He was made a knight of the Garter in 1541, and in 1543 joined the English army in France, where by his gallantry and feats of arms he gained the title of field marshal. He captured Boulogne, was made its Governor, and gained other victories, but was recalled to England after some slight reverses at Saint-Etienne. His influence at Court was no longer so powerful as in the life of his youthful friend and companion the Duke of Richmond, Henry's natural son, and charges of treasonable ambition in aspiring to the royal succession were constantly urged against Surrey and his father by the Hertford faction. In 1546 the two were arrested; Norfolk was sent to the Tower, and Surrey, on the most trivial charge, was beheaded in 1547. Though not primarily a man of letters, his work in that field left a more abiding impression than his exploits as a soldier. He wrote many amatory verses and elegies in the Italian manner, but his chief service to English literature lay in the insight with which he enriched its poetry by the introduction of the verse forms which had already received a higher development in Italy. His translation of two books of the *Æneid* gave the language its most powerful and characteristic poetic form, blank verse; and the sonnet which Shakespeare used, consisting of three quatrains and a couplet, was also introduced by Surrey. The peculiar excellence of his work was in the insight with which he not only adopted but also adapted these forms, making them harmonize with the genius of the English language. The best known edition of his verse and that of Wyatt, including a memoir, is by Nott (London, 1815-16; new ed. 1871); there is also the Arber reprint of *Tottel's Miscellany*, in which the work of both of them first appeared. Consult also an essay in Hales, *Folia Literaria* (London, 1893).

SURROGATE (Lat. *surrogatus*, *subrogatus*, p.p. of *subrogare*, *surrogare*, to substitute, from *sub*, under + *rogare*, to ask). A judicial officer having jurisdiction over the probate of wills, the administration and settlement of decedents' estates, and in some States the power to appoint and supervise guardians of infants and other legally incompetent persons. As the derivation of the name indicates, a surrogate was formerly the substitute or representative of another official. Originally in England the ecclesiastical courts had jurisdiction of all the matters above mentioned, and as their business increased it became necessary for the bishops to delegate some one to act in their places. These substitutes were at first ecclesiastical, and at a later period lawyers, and were known as surrogates. In 1857 the probate jurisdiction of the surrogates was transferred to the Court of Probate and Divorce.

Prior to the Revolution the Governors of the various American colonies were accustomed to appoint surrogates to represent them in matters of probate and administration of estates. In New York and several other States to-day the surrogate of a county is an independent judicial officer. The jurisdiction of a surrogate is usually confined to the probate of wills, the administration of the estates of persons dying intestate, and the appointment of guardians for infants and other incompetent persons. Incidentally they must hear contests of wills, and controversies over the descent and distribution of property of decedents. They exercise a close supervision over the conduct of guardians' affairs, and the latter may apply to them for advice in case of doubt on any matter pertaining to their trusts. Proceedings before a surrogate are conducted with practically the same formality as in other courts. An appeal from the decisions of surrogates will lie to appellate courts. Surrogates correspond to probate judges and judges of widows' and orphans' courts in some States. See COURTS; PROBATE COURT; and consult the authorities there referred to.

SURTEES, sûr'tēz, ROBERT (1779-1834). An English antiquary, born at Durham. He graduated B.A. from Christ Church, Oxford, in 1800; then studied law at the Middle Temple. On the death of his father (1802) he gave up the law and settled on the family estate at Mainsforth, a small village in the County of Durham, where he lived in retirement. Surtees devoted his life to his *History of Durham* (vol. i. 1816; vol. ii. 1820; vol. iii. 1823; vol. iv., ed. by James Raine, 1840). This is a careful and exhaustive work, and is written in a readable style. Surtees was also an adept at composing ballads which were playfully palmed off as ancient. Scott himself was deceived by *The Death of Featherstonehaugh*, which was inserted in the *Minstrelsy of the Scottish Border*. As a memorial, the Surtees Society was established in 1834 at Durham for publishing unedited manuscripts bearing on the history of the northern counties of England from the earliest period to the Restoration. Consult the *Life of Surtees*, by G. Taylor (Surtees Society, Durham, 1852).

SURVEY. See SURVEYING; GEODESY; COAST AND GEODETIC SURVEY, UNITED STATES; GEOLOGICAL SURVEY, UNITED STATES.

SURVEYING (from *survey*, from AF. *surveer*, *survoir*, from Lat. *supervidere*, to overlook, oversee, from *super*, above + *videre*, to see). The art of ascertaining by measurement the shape and size of any portion of the earth's surface, and representing the same on a reduced scale on maps in a conventional manner. Surveying is supposed to have originated in Egypt, where property boundaries were annually obliterated by the inundations of the Nile. In Rome surveying was considered one of the liberal arts, and the measurement of lands was intrusted to public officers (*agrimensores*) who enjoyed certain privileges; and it is probable that the system of measurement practiced by them was similar to the cruder methods of plane surveying practiced at the present time. The higher development of surveying method is of comparatively recent date.

Surveys are broadly separated into two classes, determined by the extent of the area surveyed. Most surveys comprise the measurement of comparatively small areas in which all practical refinements are met if we consider the areas absolute planes, neglecting the curvature of the earth's surface. The methods of measuring such areas is usually denominated plane surveying. Certain surveys of modern times, however, include areas so large that it is necessary to take into account the curvature of the earth's surface, and the methods of measuring such areas are termed geodetic surveying or geodesy (q.v.).

Briefly summarized, plane surveying includes land surveying, topographic surveying, and hydrographic surveying (see HYDROGRAPHY), mining surveying, railway surveying, and city surveying. Geological surveying is a development of topographical surveying in which the outcrops of the earth's rock formation are located and denoted on topographical maps. Geodetic surveying is a class by itself, as is also photographic surveying (q.v.).

PLANE SURVEYING.

LAND SURVEYING. As at present practiced all surveys of land, properly so called, are made: (1) to establish certain monuments, corners, lines, and boundaries, so as to lay out and divide land; or (2) to identify and locate such monuments, lines, and boundaries after they have been established, as in all resurveys for location and area. In all cases of land surveying the boundaries and dividing lines are the traces of vertical planes on the surface of the ground, and the area is the area of the horizontal plane included between the bounding vertical planes. In other words, the area sought is not the real surface, but the horizontal projection of that surface. In laying out land, the work consists in running the bounding and dividing lines over all the irregularities of the surface, determining their bearings and horizontal distances and leaving temporary and permanent marks. The bearing of a line is the horizontal angle it makes with a meridian plane through one extremity, and it is determined by means of a surveyor's compass. The length of the line is usually determined by measurement with a surveyor's chain. (See ENGINEERING INSTRUMENTS.) The marks by which the line is physically denoted are various, such as stones, stakes, holes, mounds, or trees, specially marked and described. These marks, whatever their character, are called monuments, and should be of distinctive and permanent character.

The true meridian of a place may be obtained by astronomical observations and the deviation of the magnetic meridian determined. This deviation is called the declination, or variation, of the magnetic needle. The compass is usually provided with a vernier-scale (see VERNIER) for turning off the variation so that the needle may indicate the true meridian if desired. An instrument called the solar compass, invented by Burt (1836), determines the true meridian by a single observation, the sun being on the observer's meridian. This instrument has been adopted by the United States Government for use in surveying the public domain. The declination varies from year to year and is an essential element to be recorded in the field-notes so as to enable the surveyor at any future time to retrace the original survey.

The system of laying out the United States public lands furnishes a good example of the methods of laying out land on a large scale. This system probably was devised by Gen. Rufus Putnam, of Revolutionary War fame, and was first used in laying out the eastern portion of the State of Ohio in 1786-87. The reference lines employed in these public land surveys are in each case a principal meridian and a base line, the meridian running, of course, north and south, and the base line running east and west. From the principal meridian and its accompanying base line guide meridians are run north and south from the base line 24 miles apart, and standard parallels are run east and west from the principal meridian 24 miles apart. These lines are run with great care, the solar compass being employed. Every mile is marked by a monument and is called a 'section corner,' and every sixth mile has a different mark and is called a 'township corner.' From each township corner on any standard parallel, auxiliary meridians are run north to the next standard parallel. Since these meridians converge somewhat toward the principal meridian, they will not be quite six miles apart when they reach the next standard parallel, and, therefore, to run the next series of auxiliary meridians north, the start is made not at the points where the first series terminate, but at the six-mile points previously marked off. Where the auxiliary meridians have been lined out, the land is divided into a series of strips running north and south, and six miles wide. These are called 'ranges.' The next step is to cut these ranges transversely by running east and west lines at six-mile intervals. The land is thus divided into squares measuring six miles on each side. These squares are called 'townships,' and each contains 36 square miles, or 23,040 acres. The next step is to run meridians and parallels one mile apart to divide the township into 36 sections. Monuments are set at intervals of one-half mile on the lines to divide each section into quarter sections. The quarter section is the smallest primary division of the public land surveys.

The determination of areas between known boundaries is accomplished in several ways, but the one commonly used consists in determining the bearings and lengths of the outside boundary lines. This is done by beginning at one corner

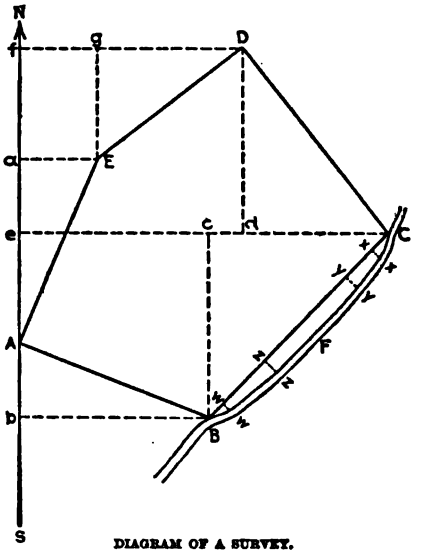


DIAGRAM OF A SURVEY.

and running around the area to the starting point, and observing the bearing and measuring the distance of each boundary line in the order in which it is encountered. To illustrate, reference will be made to the diagram, in which the lines A B C D E represent the boundary of a field of land whose area is required. Beginning

at A, the surveyor proceeds around the field, obtaining by his compass the bearings, and by measurement with a surveyor's chain, the lengths, of the lines A B, B C, C D, D E, and E A, one after the other in the order named. This being done he states these bearings and distances on paper, giving the figure A B C D E shown by the sketch. He next draws a meridian line NS through the westernmost corner of his boundary, and draws the various perpendiculars shown by the broken lines. These perpendiculars represent what are known as the latitudes of the several lines; thus for line DC, dD is the latitude, Dc is the departure, and (fD + dC) is the double meridian distance. Knowing the bearings and lengths of the various courses by simple trigonometrical calculation, the surveyor is enabled to calculate the latitudes, departures, and double meridian distances. This being known, the following rule is used for calculating the area: Twice the area of the figure is equal to the algebraic sum of the products of the double meridian distances of the several courses into the corresponding latitudes, north latitude being reckoned positively and south latitude negatively. Expressed symbolically, for the figure shown, this rule is as follows: 2A = (bB + eC) Bc + (eC + fD) Dd − (bB) Ab − (aE) Aa − (aE + fD) Eg. It may often happen that one boundary of a field is not a right line, but is an irregular curved line such as the course of a stream C F B instead of by the right line B C. The area of this field is then the area of A B C D E plus the area of C F B; the surveyor when measuring the line B C measures two or more perpendiculars such as xx, yy, zz, and ww, known as offsets and extending from the line B C to the stream. These perpendiculars divide the area C F B into a number of small areas each of which approximates closely a simple trapezoid or triangle whose area is easily determined and the sum of whose areas is the area of the total tract. There is of course a slight error in this method, but it can be made so small by an experienced surveyor as to be practically negligible. Systematic methods have been devised for making field notes so as to include a register of the topographical features incident to the chain lines, the relation of these lines one to another, and a description of monuments sufficient to identify the lines in the field. A column is usually taken in the centre of each page of the field-book to represent the chain line, and the necessary notes are entered on either side. These notes if properly kept enable the surveyor to execute a topographical map of the territory surveyed, and to calculate its area.

Topographical Surveying. The topographical surveying of a region includes not only the character and geographical distribution of the surface covering, but also the exact configuration of that surface with reference to its elevations and depressions. Thus any point is geographically located when its position with reference to any chosen point and a meridian through it is found, but to be topographically located its elevation above a chosen level must also be known. In making a topographical survey, therefore, the following processes are carried out. First, the or more reference points, according to the are geographically located; second, a series precise levels are run to establish marks tain intervals whose elevations are with reference to a common datum; these established points and elevations the locations and elevations of the surface points are established by one of several methods. The final process is to plat on a map by means of conventional symbols the location of all surface objects and the elevations and depressions of the general surface. See Topographical Map, accompanying Map.

In the topographic work of the Geological Survey, and in fact in the work of all the United States Government Surveys, the reference point for geographical location is astronomical position and the datum for all elevations is mean sea level. The various reference points are connected by means of a system of triangulation, by which intermediate points are geographically located. Elevations are established by means of lines of precise levels starting from datum. On these as a skeleton the topographical survey proper is hung. The operation of determining an astronomical position consists, first, in the measurement of zenith distances of stars by means of delicate transit instruments for the determination of latitude; second, the exchange of telegraphic time signals between a known astronomical position and an unknown one for the determination of time difference, and hence the difference of longitude; and, third, the determination by astronomic observations on close circumpolar stars of the azimuth of a line, presumably a base line or side of a triangle. The measurement of a base line consists, first, in the selection of a site, the extremities of which are so situated as to permit of easy expansion by primary triangulation; second, the laying out of a site by running a line of spirit levels over it and of setting plugs or other stable measuring marks at fixed intervals; third, the ranging out of a straight line by transit or theodolite; and finally, the measurement of the length of the base by means of base bars, iced bars or steel tapes. The expansion of a system of primary triangulation consists, first, in a reconnaissance to select stations from which others are intervisible in such manner as to permit of the formation of a series of quadrilateral, pentagonal, or similar figures composed of well-conditioned triangles; second, the erection of signals and the marking of station positions by monuments; and third, the measurement of the angles at any one station to the others which are intervisible therefrom, by means of theodolites of high power. Finally, there remains the office computation whereby the lengths of the sides of the various triangles are determined, and by the aid of this and their connection with a known astronomic position and azimuth the geodetic position and coördinates of the various triangulation stations are computed. These or equivalent coördinates at important points on a traverse line are then platted on the topographic map sheets, and this furnishes the primary control for the extension of the secondary detail of the map.

The datum on which all of the representation of the relief by contours is based is mean sea level. In order that pieces of work separated by distances of 100 or 1000 miles may ultimately meet on sheet lines with homogeneity of vertical location, it has been necessary, first, to plan out series of primary triangulation for the control of the whole. These precise levels are connected with tidal gauges referred to the mean level of the sea. With these primary data in ex-

istence it is possible to commence field work in widely scattered areas, lines of spirit leveling of lesser precision being run throughout the area to be mapped at distances not exceeding six miles apart. Between these, at distances of one to three miles apart, according to the scale and contour interval, lines of flying or secondary levels are run with only such accuracy as will enable them to close upon the better levels within limits of one or two feet, an amount imperceptible in contours of 10 to 50 feet interval.

The three surveying bureaus of the Government, viz. the Coast and Geodetic Survey, the Engineer Corps of the Army, and the Geological Survey, are all engaged in running lines of precise levels throughout the country, as they are extending the related work of triangulation and topographical mapping. The skeleton of the survey being completed, the next task is to perform the topographical mapping. Starting with two or more primary triangulation stations within the area of the quadrilateral to be surveyed, a secondary scheme of triangulation is extended by plane table (q.v.) by which tertiary points are located with such frequency as to give an average of from one to three good locations per square mile, equivalent to the same number per square inch of map. Elevations are determined of all triangulation points, which are chiefly hill summits, by vertical angulation depending on spirit leveling. Also of all the lower relief of the country by lines of spirit levels run from three to six miles apart. Where the lack of surface relief or the density of forests is unfavorable to the execution of triangulation, the primary and secondary control consists of a system of primary traverses checked by astronomical positions or primary triangulation locations. A second system of horizontal control consists of odometer traverses of all roads and trails, or, where these are not sufficient, of stadia or taped traverses across country and about the shores of lakes and streams. These traverse lines are run by compass and plane table, and are platted upon the board as the work progresses, and are adjusted upon the map, between the frequent locations resulting from the primary traverse or the plane-table triangulation. The distances between check points on such traverse are so relatively short, being one to four miles, that the error of location is hardly perceptible upon the scales of one or two miles to the inch, and an adjustment to the better positions becomes easily possible. The primary triangulation and precise leveling is executed a season in advance of the topographic mapping. The determination of secondary positions by plane-table triangulation, road and stadia traverse, and flying levels proceeds together a little in advance of the sketching of the map, but by members of the same party. The results of the adjustment and transfer of all traverse lines and level elevations to the secondary locations is a control or sketch sheet upon which are two to five trigonometric locations per square inch, from four to eight inches of road traverse per square inch, and an average of one to two instrumental elevations per square inch. Placing himself at a known position, the height of which is already determined, the topographer sketches, with the aid of hand level and by eye, the plan of the contour line passing through his position on the map, and it may be possible to locate this for a distance of half a mile, the equivalent of half an inch, in either direction. If the country be wooded it cannot be seen beyond his absolute position. Proceeding now over the road, preferably by vehicle, he stops at greater or lesser intervals, according to the amount of change of slope, carrying differences of elevation for short distances between check points by aneroid. When good elevations are insufficient more are procured by flying levels or by vertical angulation, as the work progresses. In this way a network of topographic contouring is built up everywhere along the lines of the roads, and these are frequently so near together that the contours meet and fill up the entire surface of the map. Otherwise the topographer walks in between roads, pacing distances if short, or runs stadia line, if necessary, and thus he fills in the interior of the road circuits and completes the map. This general method is necessarily much modified, according to the conditions.

MINING SURVEYING. Mining surveys are of two classes: (1) surveys to determine the surface location and boundaries of mining claims; and (2) underground surveys to determine connections, lay out work, establish the relations of the underground workings to the surface lines, points, and so on, and measure the ore removed or still in the mine. The surface methods employed are substantially land surveying methods as modified by the local and general mining laws. The underground surveys comprise carrying surface locations underground, lining on the galleries and shafts, running levels, etc., and laying out tramways and railroads. This work is ordinarily carried on much the same as it is on the surface.

CITY SURVEYING. The methods described in the section on land surveying are adequate to the needs of the city surveyor, except that, on account of the value of the land, greater accuracy should be secured. To this end, the transit instrument is used instead of the compass and the steel tape instead of the chain.

BIBLIOGRAPHY. The literature of surveying is extensive. A concise technical treatment of the whole subject is contained in Johnson, *Theory and Practice of Surveying* (New York, 1900). Other books of equal value in their particular field are: Wilson, *Topographic Surveying* (New York, 1900); Merriman, *Precise Surveying and Geodesy* (New York, 1899) and *Geodetic Surveying* (New York, 1892); and Gribble, *Preliminary Surveys and Work Estimates* (London, 1897). The voluminous reports of the Coast and Geodetic Survey, the Geological Survey, and the Engineer Corps, United States Army, contain an enormous mass of information relating to their surveys throughout the United States. Many important articles on surveys and surveying are also to be found in the proceedings of the engineering societies and in the volumes of the principal engineering journals. See GEODESY; MAP; ENGINEERING INSTRUMENTS; ENGINEERING, MILITARY; PHOTOGRAPHIC SURVEYING; LEVELING; COAST AND GEODETIC SURVEY; GEOLOGICAL SURVEY; PLANE TABLE; STADIA; etc.

SURVEYING, MARINE. See HYDROGRAPHY.

SURVEYS, NATIONAL. See GEOLOGICAL SURVEY, UNITED STATES; COAST AND GEODETIC SURVEY, UNITED STATES.

SURVIVORSHIP. A term commonly employed to describe a doctrine prevailing in some jurisdictions to the effect that where two or more

persons perish in the same accident or calamity there is a presumption of law that the stronger of them survived the others. This doctrine originated in the Roman and civil law, but generally no presumption exists in England or most of the United States, and a person seeking to establish the survivorship of one who lost his life with others in the same peril must do so by logical and relevant evidence as in any other case, or he will fail to sustain the burden of proof resting upon him. This proof need not be direct; the facts and circumstances may be shown if they furnish any reasonable basis for a conclusion. See PRESUMPTION; EVIDENCE.

SURVIVORSHIP, RIGHT OF. The right of a person holding a title jointly with another to succeed to the latter's rights upon his death, by operation of law. This right exists in case of joint tenancies, in the absence of statutes to the contrary; in a husband and wife where they hold real property as tenants by the entirety; and in surviving partners after the death of another for the purpose of winding up the business, and in some forms (tontine) of life insurance. See PROPERTY; JOINT TENANCY; PARTNERSHIP; INSURANCE.

SŪRYA, sōōr'yȧ (Skt., sun). In Hindu mythology, the god of the sun in its physical aspects. He is honored in the hymns of the Rig-Veda. (See VEDA.) All creatures depend on him, for he drives away disease and upholds the sky. He watches over mankind and beholds their deeds. His father is variously said to be Dyaus, the sky, or Indra (q.v.), or Soma (q.v.). On the other hand, he is the son of Aditi or of Ushas (q.v.), who is also regarded in other hymns as his wife, who bears the Asvins (q.v.). In later mythology Surya is the son of the sage Kasyapa and Aditi. He married Sanjna, who, overpowered by his radiance, left him, substituting for herself Chaya (Shadow). When he discovered this, he prevailed on his wife to return, and at his request his father-in-law, Tvashtar, the artificer of the gods, ground off one-eighth of his brightness, from which were made the disk of Vishnu (q.v.), the trident of Siva (q.v.), and other divine implements. He is still worshiped on the first Sunday of the month of Magha (January-February), although he has degenerated into a petty godling in modern times. Consult: Macdonell, *Vedic Mythology* (Strassburg, 1897); Wilkins, *Hindu Mythology* (London, 1900).

SŪRYASIDDHĀNTA, sōōr'yȧ-sĕd-hän'tȧ (Skt., text-book of the sun). The earliest Hindu astronomy that has been preserved. It is written in verse and contains fourteen chapters, furnishing a complete system which remains the chief authority in India for the adherents of the Hindu science of astronomy. The work has been considerably altered in content in course of time. It is probable that Greek astronomy exercised some influence over this as over the succeeding Hindu works on this science. The *Sūryasiddhānta* has been published repeatedly in India, the best edition being that by Hall and Deva Sastri (Calcutta, 1859). It has been translated into English by Deva Sastri (ib., 1860), and by Burgess and Whitney in the *Journal of the American Oriental Society*, vol. vi. (New Haven, 1860). Consult Thibaut, *Astronomie, Astrologie und Mathematik* (Strassburg, 1899).

SU'SA (Lat., from Gk. Σοῦσα, *Sousa*, Heb. *Shūshan*, Pers. *Shūs*). The capital of the Province of Susiana or Elam in Persia, a royal residence, and one of the most important cities of the ancient East. The site, 21 miles southwest of Dizful, in the modern Province of Khuzistan, is on a hilly plateau between the Ab-i-Kerkhah (the ancient Choaspes) and the Shaur (the ancient Eulæus) (Map: Persia, C 5). It is marked by the so-called tomb of Daniel, a pilgrimage shrine of repute, which in reality is a comparatively modern Mohammedan mausoleum, and by the Kaleh-i-Shus (fortress or acropolis of Susa) with ruins that cover a space of about three miles and consist of three spacious artificial platforms more than 100 feet high. The name of Susa occurs on Assyrian monuments of the time of Asshurbanipal (B.C. 668-626), who captured it. At first under Babylonian dominion, it came, at the time of Cyrus, under Persian rule; and the Achæmenian kings raised it to the dignity of a metropolis of the entire Persian Empire. When Babylon had risen again to importance under Alexander and his successors, Susa gradually declined. In the Arab conquest of Persia it held out bravely for a long time, defended by Hormuzan. During the Middle Ages it was still inhabited and known for its manufactures of sugar. Excavations by Williams, Loftus, Churchill, Dieulafoy, and others, have revealed a citadel of semicircular form, and the remains of the extensive colonnade, with a frontage of 343 feet and a depth of 244 feet, of the great palace built by Darius Hystaspis (B.C. 521-485), and restored by Artaxerxes Mnemon (B.C. 405-362), after having been ruined by fire in the reign of Artaxerxes Longimanus (B.C. 465-424). Cuneiform inscriptions, friezes of lions and archers, finely colored, now in the Museum of the Louvre at Paris, and numerous other relics have been recovered. Consult: Dieulafoy, *L'Acropole de Suse d'après les fouilles exécutées en 1884, 1885, 1886, etc.* (Paris, 1890-92); and Billerbeck, *Susa* (Berlin, 1892).

SUSA, sōō'zȧ (Lat. *Segusio*). A city in the Province of Turin, Italy, 32 miles by rail west of the city of Turin, on the Dora Riparia (Map: Italy, B 2). It has a triumphal arch 44 feet high, dedicated, the inscription reads, in A.D. 8 to Augustus. It was formerly of strategic importance, being regarded as the key to the Alpine roads over Mont Cenis and Mont Genèvre. Population (commune), in 1901, 4957.

SUSA. A port of Tunis, on the Gulf of Hammamet, in the Mediterranean Sea. It is 32 miles east-northeast of Kairwan, with which it is connected by rail, as also with Tunis (Map: Africa, F 1). It is surrounded by old walls, and its lofty, ancient, and restored citadel is used as the French military headquarters. In the neighborhood are large plantations of olives and grapes. The roadstead is bad. Susa is on the site of the Roman city of *Hadrumetum*. Population, about 12,000.

SUSAN'NA (Gk. Σούσαννα, *Sousanna*, from Heb. *shūshan*, lily), HISTORY OF, also known as THE JUDGMENT OF DANIEL, and as SUSANNA AND THE ELDERS. One of three apocryphal additions to the Book of Daniel in the Greek Bible, the others being *The Song of the Three Holy Children* and *The History of Bel and the Dragon* (q.v.). The story of Susanna is as follows: In

the early days of the Babylonian captivity there lived a woman, Susanna by name, who was celebrated for her beauty and her virtue. She was the wife of Joiachim, a wealthy and respected man, and daughter of a priest, Hilkiah. Two elders, who were also judges and held in high repute, were seized by desire for Susanna, and, meeting each other unexpectedly in Joiachim's garden, agreed to coerce her. Susanna refused to listen to them, and in revenge the elders accused her of adulterous relations with a young man who had fled when surprised by their sudden appearance. She was condemned to death on this evidence, but Daniel, then a very young man, appeared and undertook to prove Susanna's innocence. By questioning the witnesses apart and showing discrepancies in their testimony he succeeded. The people applauded Daniel and put Susanna's accusers to death. There is nothing to warrant the supposition that the story was originally written in Hebrew or Aramaic. In most manuscripts it precedes the first chapter of the Book of Daniel, and so we find it in the old Latin and Arabic versions; but the Septuagint, the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac place it at the end of the book, and reckon it as the thirteenth chapter. Consult: Ball, in the *Speaker's Apocrypha*, vol. ii. (London, 1888); Fritzsche, *Apokryphen* (Leipzig, 1871); Zöckler, *Apokryphen des Alten Testaments* (Munich, 1891); Kautzsch, *Apokryphen und Pseudepigraphen des Alten Testaments* (Tübingen, 1899 et seq.).

SUSEMIHL, zōō'ze-mēl, FRANZ (1826-1901). A German classical scholar, born at Laage, in Mecklenburg-Schwerin. He was appointed professor of classical philology at the University of Greifswald in 1856. Among his works the most valuable are: *Die genetische Entwickelung der Platonischen Philosophie* (1855-60); text editions of Aristotle's *Politics* (with German translation, 1879); the *Ethica Nicomachea* (1880); and a *Geschichte der griechischen Litteratur in der Alexandrinerzeit* (1891-92). The last work is regarded as one of the most popular and trustworthy treatises on the subject.

SUSO (zōō'zō), or **SEUSE,** HEINRICH (c.1295-1366). A German mystic. He was born at Ueberlingen, Baden. At the age of thirteen he entered the Dominican Order and spent most of his life in monasteries at Constance and Ulm. He was impulsive and an enthusiastic disciple of Eckhart (q.v.), but gives the master's speculative ideas a spiritual expression. He was truly called 'the sweet' Suso on account of his poetry and child-like religion. He was not a member of the Brethren of the Free Spirit, as has sometimes been supposed. His *Autobiography* and his *Book of Everlasting Wisdom* have been translated into many languages, and are both of unique importance for the study of the psychology of mysticism. He died at Ulm, and was beatified by Gregory XVI. in 1831. Consult Diepenbrock, *Heinrich Suso: Leben und Schriften* (Regensburg, 1829, 1837, and Vienna, 1863). A more critical edition of Suso's works is that by Denifle (Augsburg, 1878), and there is an English translation (London, 1865).

SUSPENSION (Lat. *suspensio*, from *suspendere*, to hang, from *sub*, under + *pendere*, to hang). A term in music. A note is said to be suspended when it is continued from one chord to another to which it does not properly belong, and to a proper interval of which it must eventually be resolved.

SUSPENSION BRIDGE. See BRIDGE.

SUSPENSOR (ML., that which suspends, from Lat. *suspendere*, to hang). A special, usually filamentous organ developed by and at the base of the embryo, which is thereby related more effectively to its food supply. The suspensor chiefly appears among seed-plants, its largest development occurring among the conifers. See EMBRYO.

SUSPICIOUS HUSBAND, THE. A comedy by Benjamin Hoadly, produced in 1747. Strickland, the husband, is made jealous by the intrigues of two attractive visitors in his home, in which he fancies his wife involved.

SUSQUEHANNA, sŭs'kwe-hăn'ȧ. A river draining the greater part of Pennsylvania (Map: Pennsylvania, E 4). It rises in Otsego Lake in central New York, and flows southward in three large zigzag bends across Pennsylvania and into Maryland, where it empties into the northern end of Chesapeake Bay at Havre de Grace after a total course of more than 400 miles. It is almost throughout a shallow, swift, and unnavigable stream, but its whole course is through very picturesque country as well as through some of the most populous industrial and mining regions. After flowing through the northern plateau it enters the anthracite districts of the Appalachian valley. First it follows one of the western longitudinal valleys, and then turning to the southeast it breaks through all the Appalachian ridges, after which it traverses the more open but still picturesque Piedmont plain. It receives its chief tributaries from the west, the Chemung, which joins it near the New York boundary, the large West Branch, 200 miles long, and the Juniata. Its lower and middle course is followed by a lateral canal, but its only importance as a waterway is for floating lumber. The traffic along its valley is carried chiefly by the railroads which follow its course throughout its length. The chief cities on its banks are Harrisburg and Wilkesbarre in Pennsylvania, Port Deposit in Maryland, and Binghamton in New York. The principal city on the West Branch is Williamsport.

SUS'SEX. A southeastern maritime county of England, bounded on the north by Surrey and Kent, on the south by the English Channel, and on the west by Hampshire (Map: England, F 6). Area, 1458 square miles. Population, in 1891, 550,446; in 1901, 605,052. The South Downs traverse the county from west to east, ending about 20 miles east of Brighton, in the lofty cliff of Beachy Head, and the northern escarpment of the Downs leads down to the fertile and richly wooded district of the Weald. The chief rivers are the Arun, Adur, and Ouse, which rise in the north of the county, and flow south into the Channel. A remarkably productive tract of land extends west from Brighton along the coast to the Hampshire border; and in the southeast of the county the rich marsh lands that line the coast make excellent pasture grounds. The Down-lands are covered with a fine, short, and delicate turf, on which the well-known breed of Southdown sheep are pastured. The principal industries of the county are agriculture and cat-

tle-raising. Thick beds of gypsum are worked at Netherfield. Capital, Chichester.

SUSSMANN-HELLBORN, zus'män hĕl'-bôrn, Louis (1828—). A German sculptor, born in Berlin, where he studied under Wredow and settled in 1857 after a sojourn in Rome (1852-56). Of his genre and mythological subjects, a "Drunken Faun" (1856) and "Sleeping Beauty" are in the National Gallery, while his monumental work is represented by statues of "Frederick the Great in Youth" (1862), City Hall, Breslau; "Frederick the Great in Mid-age" and Frederick William III. (both 1869), City Hall, Berlin; "Holbein" and "Peter Vischer," both in the Art-Industrial Museum, Berlin, which he helped to establish in 1867. He was artistic director of the Royal Porcelain Factory in 1882-87.

SUTECH, sōō'tĕk. An Egyptian deity. See Set.

SUTH'ERLAND. A northern county of Scotland, bounded on the east by Caithness and the North Sea, on the north and west by the Atlantic, and on the south by Ross and Cromarty (Map: Scotland, D 1). Area, 2028 square miles; population, in 1891, 21,896; in 1901, 21,440. The coast line is 60 miles in extent, and the shores, rugged on the north and west, where they are broken by the force of the Atlantic, are comparatively flat on the east. The southern and central regions of Sutherland are the most elevated; the principal mountain peaks are Ben More in Assynt (3273 feet) and Ben Clibrigg (3154 feet). The chief rivers are the Oikel and the Shin. Extensive moors stretch across the county; and the rivers and lakes, the chief of which is Loch Shin, form numerous low-lying valleys or straths. In the eastern districts the soil is very fertile, yielding all kinds of agricultural produce. Coal, granites of various colors, marble, limestone, etc., are found; there are good salmon, herring, and other fisheries. The capital is Dornoch.

SUT'LEJ, or **SATLEJ.** The chief tributary of the Indus. It rises in the southern part of Tibet near the sources of the Indus and the Brahmaputra, and, after breaking through the main range of the Himalayas, it flows southwest through the great arid plains of the Punjab, joining the Indus in the southwesten part of that province after a course of about 950 miles (Map: India, B 3). After passing through Lake Manasarowar (q.v.) the river, whose upper course is very rapid, flows through a series of lofty and highly picturesque mountain valleys. In the low 'doabs' of the Punjab its waters are largely used for irrigation, but its volume is nevertheless almost equal to that of the Indus. The Sutlej is the eastern and southernmost of the 'Five Rivers of the Punjab,' the other four being its two main tributaries, the Beas and the Chenab, together with two branches of the latter. Below the confluence of the Beas the river is known as the Ghara, and its lowest course, after receiving the Chenab, is called the Panjnad, or Five Rivers.

SŪTRA, sōō'trȧ (Skt., thread, string, clew). In Sanskrit literature, the technical name of more or less brief, aphoristic rules, and works consisting of such rules. The *sūtra* style of writing is preëminently the scientific style of India. The object of the *sūtras* is to supply a short survey of the facts of any given science in a form so brief that the whole theme may be memorized. In the later works of this class brevity and allusiveness are carried to such an excess that, but for the aid of commentaries which regularly accompany them, they would be obscure and sometimes absolutely unintelligible. Probably this peculiar style of writing originated with the methods of teaching which have prevailed in India from the earliest time. The school work is purely mnemonic; the teacher recites, and the pupil learns by heart piecemeal. It seems, therefore, likely that the *sūtras* were intended as memorial sentences which the pupil had to learn by heart, in order to obtain a grasp of the outline of his subject, as well as the fuller explanation which his teacher appended to it orally.

The importance of the *sūtras* will be understood from the fact that they form in very early times the standard medium of most of the ritual, legal, grammatical, metrical, and philosophical literature. The ritual *sūtras*, known as *Śrāuta Sūtras* and *Gṛhya Sūtras*, are systematic compendiums of the priestly sacrifices and the homelier religious practices of the householder respectively. The *Dharma Sūtras*, the oldest sources of Indian law, are also rooted in the Veda (q.v.). There is another class of Vedic *sūtras*, concerned with religious practice, the *Śulva Sūtras*, of which class the last chapter of the great Vedic *sūtra* collection of the school of Apastamba is an example. There are practical manuals giving the measurements of the altars, and so forth. They show quite an advanced knowledge of geometry, and constitute the oldest Indian mathematical works. In addition, the systematic study of the Vedas, which was prompted by the increasing difficulty of understanding and preserving the hymns, produced a series of ancillary Vedic sciences in *sūtra* style, the so-called six *Vēdāngas* or 'members of the Veda.' These are *śikṣā*, or phonetics, *chandas*, or metrics, *vyākaraṇa*, or grammar, *nirukta*, or etymology, *kalpa*, or religious practice, and *jyōtiṣa*, or astronomy. The most important class of these texts, belonging to the class *śikṣā*, phonetics, are the *Prātiśākhya Sūtras*, which deal with accentuation, pronunciation, and other matters, but are chiefly concerned with the phonetic changes undergone by Vedic words when combined in a sentence. Their observations are so minute and acute as to approach the best results of the modern science of phonetics, and they are unrivaled in their way in the whole history of antiquity. A still more important branch of *sūtra* literature is grammar, in which the Hindus again surpass all nations of antiquity. Little has been preserved of the preliminary stages of grammar. The student of native Sanskrit grammar, therefore, enters at once upon the intricate structure which bears the name of Panini (q.v.). His systematic analysis of words into roots, suffixes, and inflexional elements has been adopted with unimportant changes by modern European scientific grammar.

Later systematic philosophy, which has grown up on the basis of the theosophic hymns of the Veda and the *Upanishads* (q.v.), also adopts the *sūtra* style of presentation in the six systems of philosophy. Even so remote a theme as erotics is in the *Kāmasūtra*, or 'Love Sutra,' of Vatsyayana, naïvely treats this subject in the set form of *sūtra* rules. In one quarter, however, the *sūtra* has abandoned its typical style and has

become the reverse of brief, for the Buddhist *Sūtras*, or *Suttas* (see PITAKA), the sermons ascribed to Buddha, excel in prolixity almost every other type of literature in existence.

SUTRI, sōō'trē (anciently **SUTRIUM**). A town in the Province of Rome, Italy, 29 miles northwest of Rome. It is interesting for its ancient walls and gates, its Etruscan tombs, and the ruins of an amphitheatre dating from the time of Augustus. Sutri is known as the scene of the synod which in 1046 deposed Popes Gregory VI. and Sylvester III. Population (commune), in 1901, 2795.

SUTRO, sōō'trō, ADOLPH HEINRICH JOSEPH (1830-98). A German-American mining engineer, philanthropist, and Mayor of San Francisco. He was born at Aix-la-Chapelle, in Rhenish Prussia; came to the United States in 1850; and soon after went to the Pacific Coast. He was best known as the designer and constructor of the famous Sutro Tunnel, built to drain and ventilate the mines of the celebrated Comstock silver lode in Nevada. It is 20,500 feet long, and cost about $6,500,000. It did not prove so valuable as had been hoped, but by investing the returns which he got from it in San Francisco real estate Sutro became a millionaire. In 1880 he laid out in San Francisco the Sutro Heights Park, and he made numerous gifts to the city. He also founded the Sutro Library, containing about 250,000 volumes. In 1894 he was elected Mayor of the city by the Populists. By the terms of his will Sutro Heights was given to the city for a public park, the Sutro Library was to be opened to the public, and San Miguel ranch was given to support a scientific school. The will was, however, set aside by the courts on the ground that he was not mentally competent at the time he made it.

SUTTEE (from Skt. *satī*, virtuous wife). The practice which prevailed in India of a wife burning herself on the funeral pile, either with the body of her husband, or separately, if he died at a distance. Suttee for the orthodox Hindus is based on the injunctions of their sacred books, and there can be no doubt that various passages in the Puranas (q.v.) and codes of law countenance belief in its merit and efficacy. These, however, are all rather late texts. The custom is alluded to in Hindu literature, and classical authors refer to it as early as B.C. 316. It has even been referred to the Rig Veda as authority, and it was formerly thought that a Vedic verse had been falsified to give support to the practice. It has been shown, however, that this view is untenable. The Rig Veda does not recognize the custom. Manu (q.v.), the law-giver, does not sanction it, though it was known before his time. It appears at first to have been a royal custom and privilege, afterwards generalized and made legal. The custom was abolished by the British in 1829. Suttee is by no means confined to India. Under other names, and in other forms, the widow's death at the grave of her husband is known in many parts of the world, notably in the South Pacific, where a king's favorite wives were wont to let themselves be buried alive in his grave. Consult: Colebrook, *Digest of Hindu Law* (London, 1801); id., *Miscellaneous Essays*, vol. i. (new ed., ib., 1873); Grimm, *Kleinere Schriften*, vol. ii. (Berlin, 1849); Wilson, *Collected Works*, ed. by Rost, vol. ii. (London, 1862).

SUTTER, JOHN AUGUSTUS (1803-80). An American pioneer, born in Kandern, Baden. He was of Swiss parentage and was educated at the military college at Berne. He emigrated to America in 1834, and became a trader at Santa Fe, N. M. In 1838 he made his way to the Pacific Coast, thence to the Sandwich Islands, and finally to Alaska. Obtaining a grant of Mexican land, he established in 1841 a settlement called New Helvetia, where the city of Sacramento now stands. He was Governor of the north district of California under the Mexicans, and alcalde and Indian agent after it passed to the United States. In February, 1848, gold was discovered on his estate. The discovery, however, brought him nothing but disaster. Gold-diggers preëmpted his lands, and except an annual pension of $3000 granted him by the California Legislature he received nothing. He settled in Pennsylvania in 1873.

SUTTNER, zōōt'nĕr, BERTHA VON (1843—). An Austrian novelist, especially known for her efforts to promote peace. Born at Prague, the daughter of Count Franz Kinsky, she married, in 1876, Baron Arthur von Suttner (1850-1902), also known as a novelist, and lived with him for ten years in Tiflis. In 1891 she founded the Austrian Society of Peace-lovers, and, as its president, took a prominent part in the peace congresses at Rome (1891), Bern (1892), Antwerp (1894), and Hamburg (1897). Her novels include: *High Life* (1884; 3d ed. 1902); *Ein Manuskript* (1885); *Erzählte Lustspiele* (1889); *Die Waffen nieder* (1889; 14th ed. 1896), translated into most European languages; and its sequel *Marthas Kinder* (1902). She also wrote *Das Maschinenzeitalter* (3d ed. 1898) and *Die Haager Friedenskonferenz, Tagebuchblätter* (1900); and edits the monthly *Die Waffen nieder* (Dresden, 1892, et seq.), organ of the Peace Bureau at Bern.

SUTTON. A town in Surrey, England, four miles northeast of Epsom. Population, in 1891, 13,977; in 1901, 17,224.

SUTTON COLDFIELD. A municipal borough in Warwickshire, England, seven miles north-northeast of Birmingham (Map: England, E 4). The chief objects of interest are an ancient Early English church, the grammar school founded in 1543, and the celebrated Sutton Park, a recreation ground of 3500 acres, these two latter institutions due to the beneficence of Bishop Vesey of Henry VIII.'s reign, who also bequeathed real estate yielding an annual revenue of $15,000, which is applied to educational and charitable purposes. Population, in 1891, 8685; in 1901, 14,264.

SUTTON IN ASHFIELD. A town in Nottinghamshire, England, three miles southwest of Mansfield, known for its hosiery manufactures (Map: England, E 3). Population, in 1891, 10,562; in 1901, 14,862.

SU TUNG-P'O, or SOO TUNG-P'O, sōō'tûng'pō' (1036-1101). The name by which Su Shih, a Chinese statesman and poet, is best known. He entered public service in 1060, and soon attracted the attention of the Emperor. At his own request he was appointed Governor of Hangchow (q.v.). He opposed the reforms of Wang An-shih, then in favor at the Court, and was degraded in consequence and banished. On

the death of the Emperor in 1086 he was recalled to the capital, where he filled several high posts, becoming president of the Board of Rites in 1091. The sarcasm of his verse, however, continued to make him enemies, and, being accused of speaking ill of the Emperor, he was again banished. A new Emperor having come to the throne, he was recalled in 1101 and restored to honor, but died soon after at Ch'ang-chow, in Kiang-su. In the estimation of the Chinese, Su stands in the first rank as a poet. An edition of his works in 115 books was issued in his lifetime, and there have been many since then with commentaries and new arrangements. Copious translated extracts are to be found in Giles, *Gems of Chinese Literature* (London, 1884), and his *Chinese Literature* (New York, 1901).

SUTURE (from Lat. *sutura*, seam, from *suere*, to sew; connected with Skt. *siv*, Goth. *siujan*, OHG. *siuwan*, *siwan*, AS. *siwian*, Eng. *sew*). A term employed both in anatomy and surgery. In anatomy it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be *serrated* when it is formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see SKULL) are of this kind. A suture is termed *squamous* when it is formed by the overlapping of the beveled (or scale-like) edges of two contiguous bones. There are also the *harmonia* and *schindylesis* sutures, the former being the simple apposition of rough bony surfaces, and the latter being the reception of one bone into a fissure of another. See JOINT.

In surgery the word suture is employed to designate various modes of sewing up wounds. The term is also applied to a single stitch. Two main varieties of suture are recognized, the *continuous* and the *interrupted* suture, and from these two a great number of modifications have been made, of which the quill suture, button suture, the glover's suture, the quilt suture, and the intestinal sutures of Lembert and Duypuytren are examples. A buried suture is one which unites some deeper structure, such as a muscle or a layer of fascia, and which does not appear above the skin. It is often made of some absorbable material. Many materials are at present employed for sutures, such as silk, catgut, silkworm-gut, horse-hair, animal-tendon, and silver wire. Consult McGrath, *Surgical Anatomy and Operative Surgery* (Philadelphia, 1902).

SU'VA. The capital and chief port of the British colony of the Fiji Islands (q.v.). It is situated on the southwestern coast of Viti Levu, 1100 miles from Auckland and 1540 miles from Brisbane. There is good anchorage in a harbor accessible at all tides; wharf extension was made in 1901. There is a European population of over 1000.

SUVALKY, sōō-väl'kē. A government of Russian Poland, situated in the northeastern part. Area, 4852 square miles (Map: Russia, B 4). The surface is generally flat and interspersed with lakes. The principal river is the Niemen. The soil is mostly fertile. About one-fourth of the area is in forests, which belong chiefly to the State and are extensively exploited. The principal occupation is agriculture. Population, in 1899, 604,945, half of whom were Lithuanians.

SUVALKY. The capital of the Government of Suvalky in Russian Poland, situated on a small tributary of the Niemen, 606 miles southwest of Saint Petersburg (Map: Russia, B 4). Population, in 1899, 27,165.

SUVAROFF, sū-vä'rôf, or **SUVOROFF**, ALEXEI VASSILIEVITCH, Count (1729-1800). A Russian field-marshal. He was of Swedish descent and was born in Finland. He served in the campaigns of the Seven Years' War and was made a colonel after the battle of Kunersdorf (1759). His services in the Polish War (1768-72), in the war against the Turks (1773-74), in suppressing the uprising of Pugatcheff, and in subduing the Tatars of the Kuban (1783), gave him increased reputation and he rose to the rank of general. In the Turkish War of 1787-92 he was commander-in-chief, for the first time brought the bayonet prominently into use in the Russian army, and decided by it the battle of Kinburn (1787). At the siege of Otchakov (1788), the battle of Fokshany (1789), which he gained in conjunction with the Austrians, and the decisive victory of Rymnik (1789), his system of rapid and repeated attack by overwhelming numbers secured him complete success. For this last victory, which saved the Austrians under the Prince of Saxe-Coburg from annihilation or capture, Suvaroff was created by the Emperor Joseph II. a count of the Empire, and from his own sovereign received the title of Count Suvaroff-Rymnikski. One of his greatest successes was the storming, in 1790, of the fortress of Ismail, where the whole Turkish garrison was put to the sword. He was appointed (1791) Governor of the newly conquered provinces. In 1794 he was sent into Poland, where he completed the annihilation of the Polish monarchy by a victory won, in conjunction with Fersen, over the army of Kosciuszko, the capture of Praga, where a horrible massacre of the inhabitants took place, and the occupation of Warsaw. The grade of field-marshal rewarded these successes. Under Paul I. he fell into disgrace (1798), from his impatience of the Emperor's fantastic military regulations, and was deprived of his rank; but being restored through English influence, he commanded the army sent to coöperate with the Austrians in Italy against the French. He reached Verona in April, 1799; compelled Moreau to retire behind the Adda after defeating him at Cassano (April 27th); entered Milan (April 29th); again defeated the French under Macdonald at the Trebbia (June 17th-19th), and a third time under Joubert at Novi (August 15th), driving them out of the whole of Northern Italy. He next entered Switzerland in order to join Korsakoff and effected a toilsome march across the Saint Gotthard, in the course of which he lost one-third of his army. But Masséna defeated the army of Korsakoff at Zurich (September 25th), and Suvaroff was compelled to execute a retreat through the Grisons and Vorarlberg. For these remarkable services he received the title of Prince Italiski. In 1800 he was named commander-in-chief of the Russian armies and ordered home. He arrived in the capital, where he died May 18, 1800. He left an autobiography

in French, which was edited by Glinka (Moscow, 1819). Consult also: Smith, *Suworows Leben und Heerzüge* (Vilna, 1833-34); id., *Suworow und Polens Untergang* (Leipzig, 1858); Reding-Biberegg, *Der Zug Suworows durch die Schweiz* (Zurich, 1869); Macready, *A Sketch of Suwarrow and His Last Campaign* (London, 1851).

SUWANEE, sū-wą'nē. A river of Florida (Map: Florida, E 2). It rises in the Okefinokee Swamp in southern Georgia and flows southwest, emptying into the Gulf of Mexico, 12 miles north of Cedar Keys, after a course of 240 miles. The scenery along its banks is attractive, and the river has been celebrated throughout the country by the song, "Old Folks at Home."

SUYUTI, sōō-yōō'tē (Ar. *Abū al Faḍl 'Abd al-Raḥmān al-Suyūṭī*) (1445-1505). An encyclopædist and the most prolific writer in Arabic literature. His family was of Persian origin, but had emigrated to Egypt, where his father was a judge and professor at Cairo. Hither the son returned after the usual travels to Mecca and the centres of learning, and here he rose from one professorship to another. But at last his arrogant and dishonest conduct drove him from his position and he died in retirement. The production of great numbers of books seems to have been his affectation, and although they do not reveal genius, they are of value for the encyclopædic information they contain. About 315 titles of extant books of his are enumerated, touching upon every subject. Consult: Wüstenfeld, *Die Geschichtsschreiber der Araber* (Göttingen, 1882); Brockelmann, *Geschichte der arabischen Litteratur* (Berlin, 1899).

SVARGA, swŭr'gȧ (Skt., heaven). In Hindu mythology, the paradise of the god Indra (q.v.). It is the residence of some of the inferior gods and deified mortals, who there rest in the shade of the five wonderful trees, *Mandāra*, *Pārijāta*, *Santāna*, *Kalpavṛkṣa*, and *Harichandana*, drink *amṛta*, the beverage of immortality, and enjoy the music of the heavenly musicians, the *Gandharvas*, and the dancing of the celestial courtesans, the *Apsarasas*. Svarga is situated on Mount Meru (q.v.), and is 800 miles in circumference and 80 miles high. Its pillars are of diamonds and its palaces of gold. The inhabitants do not remain there forever, but after a lapse of years they descend to earth to be born and die according to the doctrine of metempsychosis (q.v.).

SVEABORG, svā'ȧ-bôr-y'. A fortress of Finland, Russia. See HELSINGFORS.

SVEARIKE, svā'ȧ-rē'ke. One of the three historical divisions of Sweden. It lies between Götarike and Norrland. Area, 32,589 square miles. Population, in 1900, 1,579,954.

SVENDBORG, svĕnd'bôrg. A seaport of Denmark, on the southeast coast of the island of Fünen, on the Svendborg Sound, 27 miles south of Odense (Map: Denmark, D 3). The town occupies a charming site in a hill-encircled valley. The chief industries are iron-founding, tanning, and shipbuilding. Population, in 1901, 11,531.

SVEND'SEN, JOHAN (1840—). A Norwegian violinist and composer, born at Christiania. He studied at the Leipzig Conservatory, toured extensively, later was appointed Concertmeister of the Leipzig 'Euterpe' concerts, and from 1872 to 1877 was conductor of the Christiania Musical Association. Afterwards he became Court conductor at Copenhagen, and in 1896 was appointed conductor of the Royal Theatre. His works include string quartets and quintets; symphony in D; violin concerto in A; overture to Björnson's drama *Sigurd Slembe; Carnaval à Paris*, for the orchestra; *Coronation March* (for Oscar II.); *Wedding Cantata*, for chorus and orchestra; *Carnaval des artistes norvégiens;* Norwegian rhapsodies for the orchestra; overture to *Romeo and Juliet;* Scandinavian airs for string quartet; and Romance in G, for the violin and orchestra.

SVERDRUP, svĕr'drụp, JOHAN (1816-92). A Norwegian politician, born at the Château of Jarisberg. He studied and practiced law, but from 1850, when he was elected to the Storthing, gave his entire attention to politics and became the leader of the radical peasant faction. As president of the Storthing since 1871, he violently fought against the royal prerogatives. He was called to preside over the Ministry in 1884, but did not satisfy the radical portion of his adherents, and, yielding to the combined attacks of the Conservatives and the extreme Left, resigned in 1889.

SVERDRUP, OTTO (1855—). A Norwegian Arctic explorer, born at Haarstad Farm, District of Helgeland. He followed the sea at the age of seventeen, was subsequently in command of a merchant vessel, and in 1888 joined Nansen's expedition to Greenland. In 1893 he started with Nansen for the North Pole as commander of the *Fram*, which had been built under his supervision, and when Nansen, in 1895, proceeded north on dog sledges, Sverdrup took the ship to the Arctic Sea and in 1896 back to Norway. In 1898 he led another expedition in the *Fram* as far as Cape Sable, was caught in the ice for a year, and, after advancing into Jones's Sound in the summer of 1899, was again icebound for three years. Having explored the southwest and western shores of Ellesmere Land and discovered islands north of the Peary Archipelago, he reached Goodhaven, Greenland, in August, 1902, and returned to Norway in the autumn.

SWA'BIA, or **SUABIA** (Ger. *Schwaben*, Lat. *Suevia*). A mediæval duchy in the southwest of Germany. It took its name from the Suevi, by which the Germanic people of the Alemanni (q.v.), who occupied Southwestern Germany in the third century, were also known. The name Suevia alternates with that of Alemannia as the designation of the country in the early part of the Middle Ages, but the former finally prevailed. The region occupied by the Alemanni embraced Western Bavaria, Württemberg, Baden, Alsace, and a great part of Switzerland. The bulk of the nation was subjected by the Franks at the close of the fifth century. As part of the Frankish realm, Alemannia was governed by native dukes, but the duchy was abolished before the dissolution of the Frankish Empire. The country from which Alsace and part of the Alpine territories had been detached, and which now came to be known as Swabia, was then placed under the rule of counts and *nuntii*

camera, and for a time it was nearly independent.

In 919 Swabia was constituted one of the great duchies of the German Kingdom. It comprised the region between the Rhine and the Lech and part of Switzerland. The office of duke was frequently kept in the royal family. In 1079 the duchy passed to the House of Hohenstaufen, being bestowed by the Emperor Henry IV. upon Frederick of Staufen. Under the rule of this house, which occupied the Imperial throne of Germany from 1138 to 1254, Swabia was the most wealthy and powerful of the German duchies. In 1096 Frederick of Staufen was compelled to give up to Berthold of Zähringen the Breisgau and the Imperial bailiffship in Zurich. On the extinction of the Hohenstaufen dynasty in 1268 disintegration took place and the ducal vassals (cities, prelates, counts, etc.) claimed independence except for their allegiance to the emperors. The Count of Württemberg occupied the leading place among the petty rulers. The numerous lesser lords were for the most part obliged to accept the overlordship of the House of Zähringen or of Austria. The cities, of which many had become wealthy and powerful, were striving for local independence. In 1376 some of them formed the first Swabian League, which extended beyond the bounds of Swabia. In 1405 Württemberg, Baden, and seventeen cities joined together in the League of Marbach. The two Leagues were of little importance as political powers, but they paved the way for the Great Swabian League, formed in 1488, which under the leadership of the Count of Württemberg exercised administrative and judicial authority over the whole country. During this long period of strife a considerable portion of old Swabia had passed into the power of Bavaria. In 1512 Swabia became one of the ten circles into which Germany was divided for administrative purposes by Maximilian I. The dissolution of the Great Swabian League took place in 1533. Among the many city commonwealths which arose in Swabia were Augsburg, Ulm, and Constance. The southwestern Government District of Bavaria bears the name of Swabia (or Swabia and Newburg). Its capital is Augsburg. The best general history is Stälin, *Geschichte Württembergs* (Gotha, 1882-87).

SWADLINCOTE, swŏd'lĭn-kot. A town in Derbyshire, England, 4 miles southeast of Burton-upon-Trent. Its industries comprise coal-mining and the various branches of earthenware manufacture. Population, in 1891, 13,889; in 1901, 18,014.

SWAHILI, swà-hē'lê. A Bantu people of the Kau District, Tana-Ozi Delta, British East Africa, mingled more or less in blood with Semites. They are Mohammedans and differ little from the Arabs in general culture. They number about one million. They are noted traders, and their language, the Kiswahili, is the great medium of intercourse throughout east Central Africa. Consult: Büttner, *Wörterbuch der Suaheli-sprache* (Berlin, 1890); Seidel, *Grammatik der Suaheli-sprache* (Vienna, 1891); Steere, *Handbook of the Swahili Language* (4th ed., London, 1894); Krapf, *Dictionary of the Suahili Language* (ib., 1882); Madan, *English-Swahili Dictionary* (Oxford, 1894); Delaunay, *Grammaire Kiswahili* (Paris, 1898).

SWAIN, Charles (1801-74). An English writer known as 'the Manchester poet.' He was born in Manchester, and lived all his life in England. For fourteen years he was a clerk in the dye house of his uncle; he afterwards carried on a business in engraving and lithographing. Between 1827 and 1867 he published several volumes of verse, among which are *Dryburgh Abbey* (1832), an elegy on Sir Walter Scott; *English Melodies* (1849); and the more ambitious *The Mind and Other Poems* (1832). Several of his songs, which have been set to music, are well known, as "Somebody's Waiting for Somebody" and "Tapping at the Window." Consult the edition of his poems, with portrait and introduction by C. C. Smith (Boston, 1857).

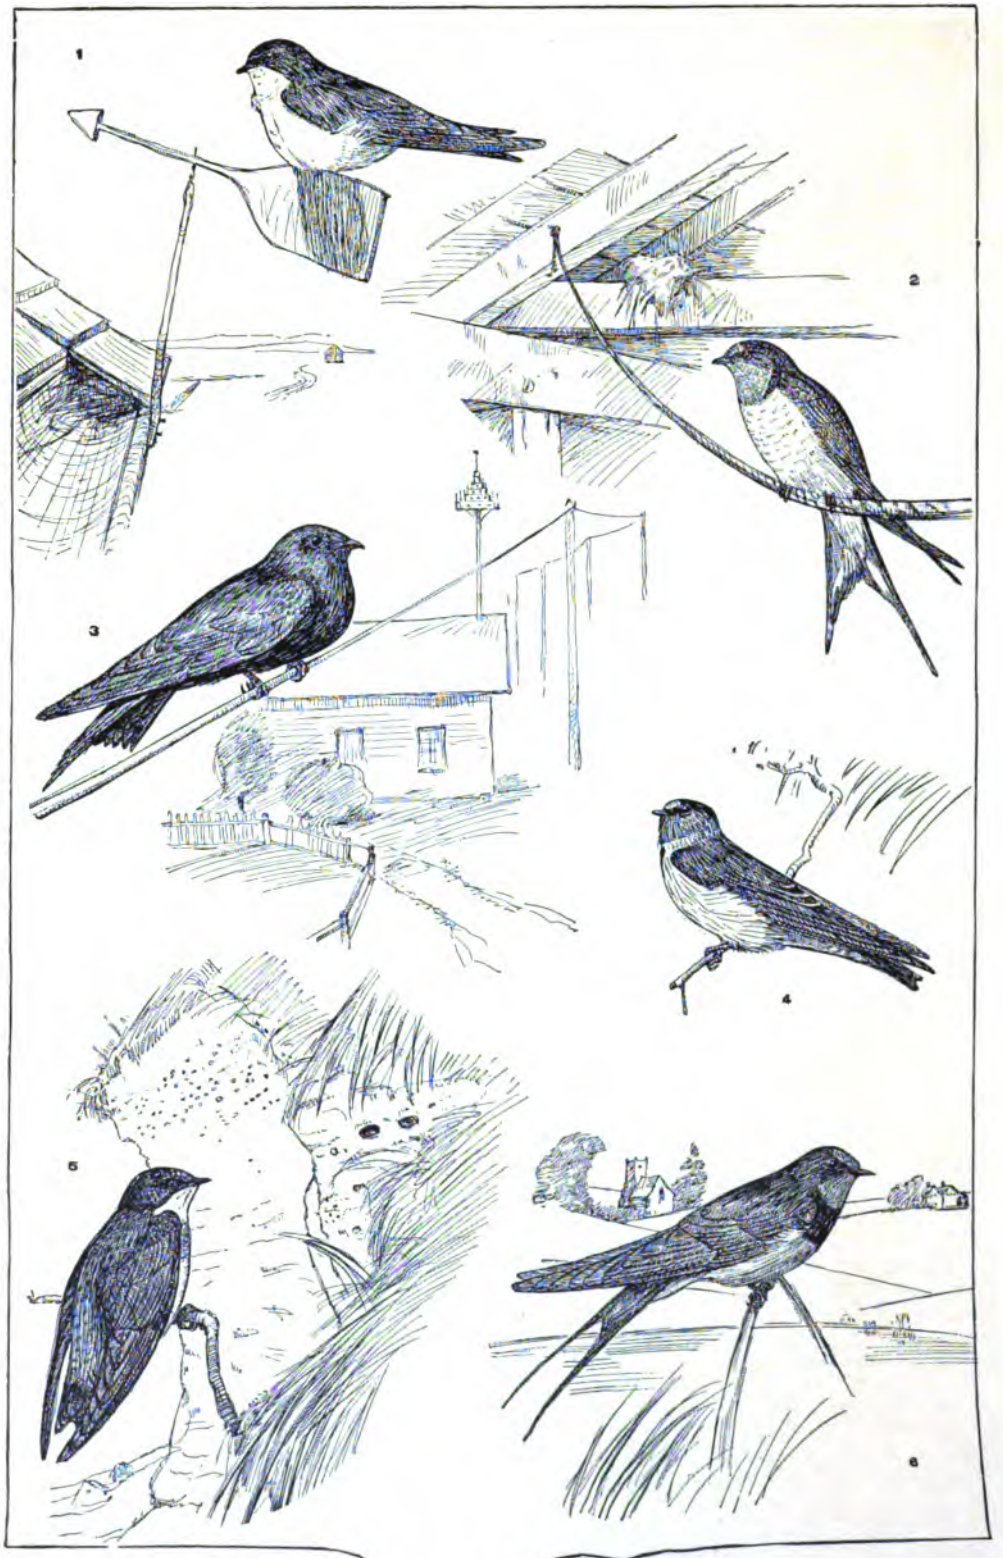
SWAIN, George Fillmore (1857—). An American civil engineer. He was born in San Francisco and was educated at the Massachusetts Institute of Technology, where he graduated in 1877. He then studied three years in the Government engineering school at Berlin, Germany. Upon his return he settled in Boston, where in 1887 he became professor of civil engineering at the Institute of Technology, and engineer to the Massachusetts Railroad Commission. In 1894 he was also made a member of the Boston Transit Commission. His most important publication is a "Report on the Water Power of the Atlantic Watershed" (vol. xvii. of *Tenth United States Census*).

SWAIN, Joseph (1857—). An American educator, born at Pendleton, Ind. He graduated at Indiana University in 1883; studied in the University of Edinburgh, and with the astronomer royal of Scotland in 1885-86; was professor of mathematics in his alma mater from 1886 till 1891; and in the latter year was called as professor of mathematics to Leland Stanford University. Two years afterwards he returned to Indiana University as president, and remained in that position until 1902, when he accepted the presidency of Swarthmore College in Pennsylvania.

SWAIN'SON, William (1789-1855). An English naturalist, born in Liverpool. He traveled in South America, and on his return to England began the publication of works on natural history. In 1841 he emigrated to New Zealand, where he became Attorney-General. Important among his works are: *Zoölogical Illustrations* (1820-23; 1829-33); *Exotic Conchology* (1821-22); *Ornithological Drawings* (1834-41); *Birds of Western Africa* (1837); *The Naturalist's Guide, etc.* (1840).

SWALLOW (AS. *swalewe*, OHG. *swalawa*, Ger. *Schwalbe*, swallow; perhaps connected with Gk. ἀλκυών, *alkyōn*, Lat. *alcedo*, kingfisher). A passerine bird of the family Hirundinidæ, a family represented by many similar species in almost all parts of the world. This family consists of birds which prey on insects, catching them in the air. They have remarkable powers of flight, now soaring to a great height, now skimming near the surface of the ground or of the water, and wheeling with great rapidity. The bill is short and weak, broad at the base, and deeply cleft, so that the gape is wide; the wings are very long, pointed, and more or less sickle-shaped when expanded, and have only nine primaries; the legs are short and weak. The tail is gener-

ally forked, and the plumage is close and glossy. The family is perhaps the most sharply defined and easily recognized of any in the order. The species are about eighty, widely diffused, being found in all countries except near the poles. Such of them as occur in the colder parts of the world are summer birds of passage, migrating to warmer regions when winter approaches and insects become scarce. Only seven species of swallow occur in North America, and all but one of these winter south of the United States, though in summer they range to the Arctic Ocean. The largest species is the purple martin, while the smallest is the bank swallow (q.v.). Perhaps the commonest of North American swallows is the barn-swallow (q.v.). Another swallow numerous about farmyards and barns is the cliff or eaves swallow (*Petrochelidon lunifrons*), whose nest is the remarkable flask-shaped structure of pellets of mud often seen attached in rows to the outside walls of barns, just under the eaves. Formerly, as in the case of other swallows (see BARN-SWALLOW), this species bred in rocky places and placed its nests in large companies against the faces of cliffs.



A large and handsome swallow common throughout North America is the white-bellied or tree swallow (*Tachycineta bicolor*), which is steel blue or green above and pure white beneath. Of the same genus is the exquisite little violet-green swallow (*Tachycineta thallasina*) of the Western United States, which is less than five inches long; the upper parts are velvety green and violet purple, while the under parts are pure white. The rough-winged swallow (q.v.) completes the list. South America has a large series of swallows very similar to those of the United States, and especially of that group of which the tree and violet-green swallows are a type. Some naturally breed in holes of rocks, others in hollow trees, or form nests of mud, straw, and feathers in some similar situation; but nearly all have abandoned their wild ways as fast as the country has been settled, and placed their abodes near or within buildings. The same pleasing habit characterizes the tribe in India, Africa, Australia, and everywhere else, and has led to the growth of much pleasant folk-lore, poetry, and sentiment. In Great Britain *Hirundo rustica*, the common or 'chimney swallow' (to be distinguished from the American chimney swift, q.v.), is much like our barn-swallow, and makes a similar nest, usually placed under a shed roof, in a half-ruined building, or often in a chimney. The geographical range of this species extends over a great part of Europe, Asia, and Africa. The window swallow, or house-martin (*Hirundo urbica*), is another very common European species, glossy black above, white below and on the rump; the feet covered with short downy white feathers, which is not the case in the chimney swallow.

Consult Sharpe and Wyatt, *Monograph of the Hirundinidæ* (London, 1885-94), which contains a description, with colored plates, of all the species of the world, and a full bibliography.

SWALLOWTAIL. Any member of a family of large butterflies, Papilionidæ, with tail-like prolongations of the hind wings. Black, yellow, blue, and green are the prevailing colors. About 25 species occur in the United States. South America is most rich in these butterflies. About 700 species have been described in all. The larvæ of the swallowtails possess a curious process on the thorax called an 'osmaterium,' which is usually retracted, but may be thrust forth at will. It is a Y-shaped process and contains a scent-gland which emits a strong odor when the organ is thrust out. The pupa is placed with the head upward, fastened by the tail to the supporting object, and is kept in place by a silk band around the middle of the body. (See BUTTERFLIES; also Plate under BUTTERFLIES, Fig. 5.) In certain species the males and females differ so much both in form and coloration that they might easily be mistaken for distinct species. In New Guinea there occurs a swallow-tail butterfly (*Ornithoptera paradisea*) the female of which is black, white, and gray, and the male is gold and green, with very long tails on the hind wings. The males of another species of the same genus are numerous and the female is rare; the proportion is said to be about 1000 to 15. Not only does the female show sexual dimorphism, but even considerable seasonal dimorphism. The tiger swallowtail (*Jasoniades glaucus*) is a North American species which shows a striking sexual dimorphism in a portion of its range. The form now known as *Turnus* is straw-colored above, banded and marked with black. In the South and West black forms of the female sex occur, and belong to the so-called '*glaucus*' form. The caterpillar of these two forms is dark green with two purple eye-spots, one on each side of the third thoracic segment, which are bordered with black, yellow, and black again in turn. When not feeding, this caterpillar rests on a bed of silk spun on a leaf. The zebra swallowtail (*Iphiclides Ajax*) presents one of the most striking cases of seasonal dimorphism known among butterflies, so that until the life-history of this form was known three different species had been described from it. There are several broods a season and the last brood winters in the chrysalis stage. The butterflies that appear in the early spring are known as the *Marcellus* form and those that appear later in the spring as the *Telamonides* form. The latter are larger butterflies with longer tails and more white than the *Marcellus* form. (See Colored Plate of AMERICAN BUTTERFLIES.) All the late spring broods produce a third form which is still larger and with longer tails. This summer brood is known as the *Ajax* form. See illustration at SKIPPER.

SWALLOWTHORN, or SEA-BUCKTHORN (*Hippophaë*). A genus of shrubs of the natural order Elæagnaceæ, natives of Europe. The commonest species (*Hippophaë rhamnoides*) is a spiny shrub often planted for ornament in sandy soil, especially near the sea. It is valued for its silvery leaves and yellow, acid, one-seeded berries, which, besides being attractive, are useful for sauces and jellies.

SWAMMERDAM, swäm'mĕr-dăm, JAN (1637-80). A Dutch naturalist, born in Amsterdam. He studied medicine at Leyden, but devoted most of his life to the study of insects and other animals. He was a skilled dissector of small animals, and was the father of the scientific study of the morphology and metamorphosis of insects. He first made a natural classification of insects by distinguishing between those which have a complete metamorphosis and those which have not. He wrote: *De Respiratione usuque Pulmonum* (1667); *Allgemeene verhandeling van*

1. WHITE-BELLIED or TREE SWALLOW (Iridoprocne bicolor).
2. BARN SWALLOW (Chelidon erythrogastra).
3. PURPLE MARTIN (Progne subis).
4. CLIFF or EAVES SWALLOW (Petrochelidon lunifrons).
5. BANK SWALLOW or SAND MARTIN (Clivicola riparia).
6. ENGLISH HOUSE SWALLOW (Hirundo urbica).

bloedeloose diertjes (1669); *Biblia Naturæ, sive Historia Insectorum in Certas Classes Redacta* (ed. Boerhaave, 1737-38).

SWAMP (AS. *swamm, swam*, swamp, Goth. *swamms*, sponge, *swumsl*, ditch, OHG. *swam*, MHG. *swam, swamp*, Ger. *Schwamm*, sponge; connected with OHG. *sumpft*, Ger. *Sumpf*, swamp, and with Gk. *σομφός, somphos*, spongy). An area of wet ground usually covered with certain coarse grasses, trees, and other plants peculiar to such land. While the direct cause for differences between typical swamps has not been fully worked out, drainage seems to be the principal controlling factor. It seems probable that in undrained swamps, such as peat bogs, the products of plant decay, including various acids, necessarily accumulate and that aëration is imperfect. Hence it seems reasonable to believe that only xerophytic plants can grow in such places. On the other hand, river swamps, which are comparatively well drained, may show reverse conditions. Since they are hydrophytic, as habitats they maintain plants whose structures are hydrophytic. (See HYDROPHYTES.) Thus undrained swamps are hydrophytic with respect to soil moisture, but xerophytic with respect to plant structures. See XEROPHYTES.

Perhaps no type of plant society better illustrates the order of succession or encroachment of one zone upon another than the most xerophytic swamps, the peat bogs or moors. A typical bog, for instance, may show a central pond with water lilies and other aquatics, surrounded by bulrushes, behind which may be a zone of sedges, and then grasses or swamp forests, e.g. of tamarack or arborvitæ. Since each of these zones in turn advances toward and encroaches upon the centre, the swamp gradually becomes filled and drained naturally in a few years.

Other characteristic xerophytic swamps are salt marshes, both the typical northern salt meadows and the mangrove swamps of the tropics. Plants of salt marshes (halophytes, q.v.) are very largely succulent. In many cases the coarse grasses resemble those of the prairies. In mangrove swamps xerophytic structures, represented typically by the mangrove leaf, are not the sole interesting features. Above the foul water many plants develop knee-like processes which supposedly are of advantage in aëration; and vivipary (q.v.) here reaches its highest expression. (See MANGROVE.) A closely allied type is the so-called cypress swamp of the Southern United States.

All swamps may be considered as ephemeral plant societies, developing either into prairies or mesophytic forests as they become better drained. Climate doubtless plays some part in this development, since the prairie rather than the forest is likely to develop in the prairie regions or in the forest regions adjoining the prairie, whereas in the heart of the forest regions most swamps eventually become covered with trees. This, is, however, not a universal explanation, since some swamps in forest regions never become sylvan.

SWAMP DEER, or BARASINGHA. A deer of Northern India, of rather large size, with smooth and somewhat flattened antlers, with a prominent brow-tine and sometimes 16 to 20 points. It is a grazer, keeps in the outskirts of the woods, and on grassy lands, and in winter gathers into small bands. Its scientific name is *Cervus Duvaucelli*. Consult Lydekker, *Deer of All Lands* (London, 1898).

SWAMP HARE, or SWAMP RABBIT. A hare of the swamps of the Lower Mississippi Valley (*Lepus aquaticus*), 24 inches long, finely mottled above with buff, rufous, and black, and more buffy than the 'cottontail;' belly and under side of tail pure white. Its habits are little known. Compare MARSH HARE.

SWAMP'SCOTT. A town, including several villages, in Essex County, Mass., adjoining Lynn and 13 miles from Boston; on Massachusetts Bay, and on the Boston and Maine Railroad (Map: Massachusetts, F 3). It is attractively situated and is known as a summer resort. There are two parks, a public library with 7500 volumes in the town hall, and the Phillips School, the most prominent building along the shore. Fishing is of some importance, but the community is engaged largely in the industries of Lynn (q.v.). The government is administered by town meetings. The water-works are owned and operated by the town. Population, in 1890, 3198; in 1900, 4548.

SWAMP WARBLER. A large genus (Helminthophila) of American warblers (q.v.), so called because of their fondness for low, swampy places. They are small, trim, insect-catching migratory birds prevailingly gray or green and yellow in color, and most of them breed north of the United States and winter in the tropics. A good example is the 'golden-wing' (*Helminthophila chrysoptera*), which is gray on the upper parts and white below, with the throat and auricular region black, and a conspicuous yellow patch on the wing.

GOLDENWING.

SWAN (AS., OHG. *swan*, Ger. *Schwan*, swan; probably connected with Lat. *sonus*, sound, Skt. *svan*, to resound). A water-bird of the duck family, the seven or eight species of which constitute the subfamily Cygninæ, composed mainly of the genera Cygnus and Olor, the latter distinguished by the great keel of the breast-bone being divided into two plates, between which lies the curvature of the windpipe—an organ greatly developed in this group. Swans are larger in body than geese, and are recognizable by their long arched necks, enabling them to reach food on the bottom of streams, and shallow ponds without diving. They nest mostly in high latitudes, constructing on the ground a rude receptacle of rushes and the like for the half a dozen greenish eggs. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish-spawn, of which they are great destroyers. They hiss like geese, and strike with their wings in attack or defense.

The typical and most familiar example of the tribe is the tame or 'mute' swan (*Cygnus olor*), which is about five feet in entire length, and weighs about thirty pounds. It is known to live for at least fifty years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish-gray plumage, and lead-colored bill, surmounted by a black knob at the base of

the upper mandible, and with a black nail. (See Colored Plate of WATER BIRDS.) In its wild state this species is found in Eastern Europe and in Asia; in a half-domesticated state it has long been a common ornament of ponds, lakes, and rivers. The ancients ascribed to it remarkable musical powers, which it was supposed to exercise particularly when its death approached. It has, in reality, a soft low voice, plaintive, and with little variety, to be heard chiefly when it is moving about with its young.

Swans, according to the law of England, are birds royal; those actually kept by the Crown had a mark, and the King's swan-herd once was an important person. The royal swans of the Thames are so marked to this day by notches and lines cut upon the beak, and the process of collecting and marking them annually is called 'upping.' Other Old World swans are the Polish, with an orange bill; the whistling swan or 'whooper;' Bewick's swan, and the aberrant black swan (*Chenopis atrata*) of Australia, which is comparatively small and deep black except the white wing-quills and the red bill.

The North American swans belong to the genus Olor. The most common species (*Olor Columbianus*) breeds in the far North and is seen in the United States only on its migrations, which extend to the Gulf of Mexico; and it is very rare east of the Alleghanies. The trumpeter swan (*Olor buccinator*), noted for its sonorous cry, breeds from Iowa and Dakota northward, and winters southward to the Gulf. It is one of the largest species, measuring 5½ feet in length. The black-necked and duck-billed swans are South American species. See DUCK, and authorities there cited.

SWAN, KNIGHT OF THE. A very old and popular myth found in French, German, and English mediæval romances, first mentioned by William of Tyre about 1180. Helias, Knight of the Swan, is one of eight children of Oriant of Lilefort. Seven are changed to swans, one drawing the hero in a boat to become champion for Clarissa of Bouillon, the ancestor of Godfrey, thus connecting the story with the Crusades. After marriage the knight departs when his wife breaks the taboo on his name, a Grail feature common to all variants, as *Lohengrin*, showing its partly Celtic origin. The scene is generally on the Lower Rhine, connecting it with the dukes of Brabant and Cleves, whose symbol was a swan.

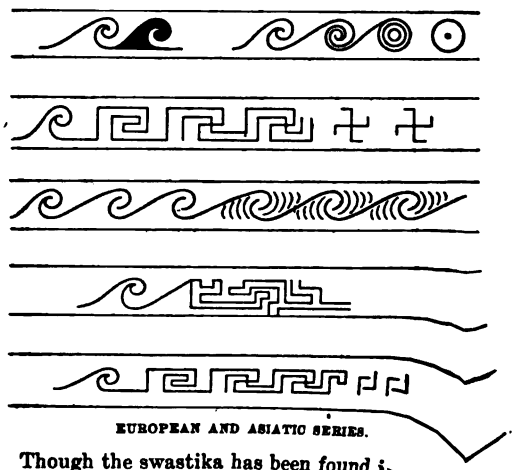
SWAN, ORDER OF THE. A religious association of princes and nobles formed in 1440 by Elector Frederick II. of Brandenburg for benevolent purposes. It was extinguished during the Reformation, but was renewed in 1843 by Frederick William IV. of Prussia as an association, open to men and women of all creeds, for the amelioration of physical and moral ills.

SWAN, JOHN MACALLAN (1847—). An English painter and sculptor, born at Old Brentford. He studied in London and in Paris. In 1889 his "Prodigal Son" (bought by the Chantrey Fund) established his reputation. His sculptured works —in nearly every material—are usually studies of cats, and his modeling is broad, flexible, and naturalistic. "The Jaguar," "Puma and Macaw," "Wounded Leopard," and "Leopard Running," challenge comparison with Barye. His subjects in oil include animals, figures, and landscapes, and are distinguished by massive, simple treatment, and a strongly imaginative element. His color is delicate and discriminating, but nearly always low in tone. Notable paintings are: "Ocelot and Fish;" "Tigers;" "Tigers Drinking;" "Ceylon Leopards;" "Lioness Defending Her Cubs;" and "Polar Bear Swimming." He was elected an associate of the Royal Academy in 1894.

SWAN, JOSEPH WILSON (1828—). An English inventor, born at Sunderland, and there educated. He made several inventions of great value, among them the carbon process for making permanent photographs, called autotypes, a miner's electric safety lamp, improvements in electrometallurgical deposition, but most notable of all the incandescent electric lamp which bears his name, the forerunner of all the electric lamps now in use. These inventions brought him many honors, including a fellowship in the Royal Society.

SWANPAN. A Chinese calculating device. See CALCULATING MACHINES.

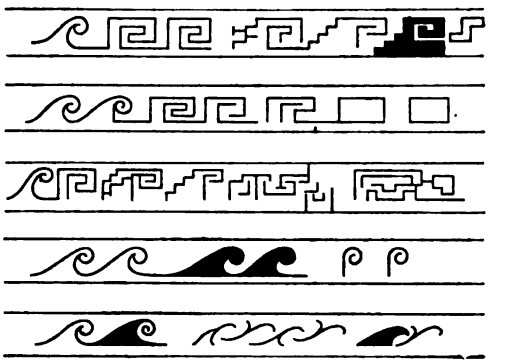
SWAN RIVER. A small river of Western Australia entering the Indian Ocean at the Fremantle, a few miles below Perth (Map: Australia, B 5). It is navigable for steamers to the latter city. On its banks was founded in 1829 the Swan River Colony, which formed the nucleus around which the colony of Western Australia was built up.



SWANSEA, swŏn'sĭ. A seaport in Glamorganshire, South Wales, at the mouth of the Tawe, 60 miles west-northwest of Bristol (Map: Wales, B 5). Swansea is the chief seat of the tin-plate trade of England, and one of the most important copper smelting and refining centres in the world. The vast resources of the surrounding coal field began to be exploited about 1830, and since that time the progress of Swansea has made it next to Cardiff the most important town in South Wales. The principal edifices, for the most part of modern construction, comprise a guild hall with the crown and law courts and municipal offices, the Royal Institution of South Wales, the grammar school founded in 1682, a good public hall, and a spacious and well-arranged infirmary. The harbor is formed by piers of masonry projecting from either side of the mouth of the Tawe into Swansea Bay, a wide inlet of the Bristol Channel. An average of 6000 vessels enter and clear nearly 4,000,000 tons of merchandise annually. In the immediate vicinity are smelting works, in which many thousands of tons of copper ores, silver ores, and zinc ores are smelted annually. About 20,000 tons of copper, valued at $15,000,000 to $20,000,000, are annually produced, and about 2,000,000 tons of tin plate, valued at $15,000,000, are exported annually. The annual value of exports and imports is estimated at $50,000,000 to $60,000,000. Swansea owes its origin to a castle erected in 1099. In 1260 the castle was burned down. It was twice rebuilt, but was finally dismantled by the Parliamentarians in 1647, and is now an interesting ruin. Population, in 1891, 90,349; in 1901, 94,514.

SWARTH, swärt, HELENE (1859—). A Dutch poet, born at Amsterdam and, since 1893, married to the poet Frits Lapidoth at The Hague. From

1865 to 1884 she lived at Brussels, and after publishing two volumes of poems in French, *Fleurs du rêve* (1879) and *Les Printanières* (1882), took high rank among the younger generation of poets in Holland with the lyrics, mostly in sonnet form, *Blauwe Bloemen* (1884), *Beelden en Stemmen* (1887), *Sneeuwvlokken* (1888), *Passiebloemen* (1891), and other collections. She also wrote sketches in prose, such as *Fronisch en tragisch* (1895), *Van Vromenleed* and *Van Vrouwenlot* (1896), *Ernst* (1902), and others.



SWARTHMORE COLLEGE. A co-educational institution at Swarthmore, Pa., 12 miles west-southwest of Philadelphia. It was founded in 1864 by members of the Society of Friends, to secure to the youth of the Society higher educational training under instructors of their own faith. The college conferred the degrees of bachelor of letters and bachelor of science until 1903, when the degrees of bachelor of arts and bachelor of science in engineering were made the only ones given. The work is partially elective, and special courses of study are provided. The master's degree in arts, letters, and science and the degrees of civil, mechanical, and chemical engineers are given for advanced work. In 1903 there were 205 students in all departments, with 25 instructors. The college library contained 22,100 volumes. The productive funds amounted to $300,000, the income to $100,000, and the total valuation of the college property to $800,000.

SWASTIKA (Skt., weal-making). A fylfot or 'four-foot' cross, a monogrammatic sign having four branches, of which the ends are bent, generally at right angles, thus  or  . It is a sign of benediction or of good luck, and in one form or another has been used as a symbol of welfare from a very early time. The sign appears in a variety of modifications, often connected in a continuous scroll, of which there are two well-defined types, forming on the one hand the European and Asiatic series, and on the other hand the American series, as illustrated by the following diagrams:

EUROPEAN AND ASIATIC SERIES.

Though the swastika has been found in Asia, and America, yet it is unknown in Europe, races. There is, for example, no evidence that it was current as a native symbol in many Babylonia, Assyria, Phœnicia, or Egypt, (till a late period) in Persia. It was particularly adopted by Buddhism and its presence in China, Japan, and Tibet can easily be explained as due to that religion. The swastika is unknown in early India (all evidence to the contrary rests on false assumptions) and when (c.300 B.C.) it first appears, it is as a simple cross, as in crossed arms.

AMERICAN SERIES.

Many of the swastikas found at Hissarlik (Troy) are now acknowledged to be no true swastikas. They are not found before the third city. Its original place and significance are alike unknown, but it has been the object of endless speculation. Some scholars see in the swastika a solar symbol, which represents, in its so-called female and male forms,  and  respectively, the annual circuits of the sun to north and south. It has been derived from the *triskalion* or 'three-leg' symbol  , but this sign is of later origin. The swastika has also been interpreted in other ways, as a wind-symbol, an earth-symbol, an emblem of productivity, a phallic emblem, etc. Temple regards it as in origin merely decorative, and suggests that the running design may have been taken from a coil of string. In the opinion of d'Alviella, who calls it, from its shape, gammadion, the swastika was chiefly talismanic. The swastika has been derived by some from the cross; by others, from the circle; it has been regarded as an evolution from the lotus-petal in architecture; and as a mystic design it has been associated with fire and with water. The sun and fecundity are its most probable sources, if it had any meaning beyond that of an ornament becoming a mystic sign. The swastika appeared first in the Bronze Age, and occurs in the Swiss lake-dwellings. In the historic period it is found in Japan, Korea, China, Tibet, Armenia, Asia Minor, Greece and its islands (especially Cyprus and Rhodes), Italy, France, Germany, Scandinavia, Great Britain (perhaps only under Scandinavian influence), North America (e.g. Ohio, Tennessee, Mississippi, Alaska), Mexico, and South America (e.g. Brazil). In assigning its original home, it must be remembered that no case of Oriental swastikas precedes the period of Greek influence in India. It seems probable that d'Alviella may be right in ascribing an eastern emigration from a western centre, if not from Troy itself. It is said that there is in Tibet a sect of rationalists called Swastikas, but this is probably an error, and the sect meant is that of the Jains.

BIBLIOGRAPHY. The literature directly or indirectly relating to the swastika is very large (more than 100 works are mentioned by Wilson), but most of it is useless, being composed by theorists rather than by careful scholars. Besides the article by R. C. Temple (referred to above), which appeared in the first number of the *Journal of the Anthropological Society of Bombay*, and d'Alviella's great work, *La migration des symboles* (Paris, 1891), there is an exhaustive treatise in the *Report* of the United States National Museum (Washington, 1894), by Thomas Wilson, *The Swastika, the Earliest Known Symbol, and Its Migrations*, which, besides giving an account of the various theories of the symbol, has a complete bibliography of the subject.

SWATOW, swä'tou' (a local corruption of Chinese *Shan-t'ow*, fish-trap head). A treaty port in the Province of Kwang-tung, Southeastern China, situated in latitude 23° 21′ N., longitude 116° 39′ E., on the left bank and near the mouth of the river Han (Map: China, E 7). It is dependent on the departmental city of Ch'ao-chow fu, 35 miles farther up the river, where the consuls are supposed to reside. It was opened to foreign residence and trade by the Treaty of Tientsin (1858), and the British and United States consuls were appointed in 1860. The foreign community is small and isolated, partly in the vicinity of the native town and partly on the hilly ground on the opposite side of the river. The natives are noted for their turbulence and their hostility to foreigners. Sugar-making is the chief industry of the region served by Swatow. Sugar is the heaviest export, and bean-cake from Niu-chwang for use as manure in the sugar fields is one of the heaviest imports of native products. There are several large sugar refineries here, and a steam flour mill. Other products are tea, grasscloth, indigo, vegetable oils, paper, tobacco, joss-sticks, joss-paper, etc. The population in 1901 was 38,000.

SWATS, swäts. A people of the Indo-Afghan frontier belonging by race and language to the Aryan stock. Their country, called Swat, traversed by the river of the same name, an affluent of the Kabul, is included in the recently constituted Northwest Frontier Province of India. Formerly Buddhists, they were converted to Mohammedanism in the eleventh century. The lower Swat country was occupied by the Yusufzais in the middle of the fifteenth century, and at the end of the sixteenth the Swats were nearly exterminated.

SWAZILAND, swä'zé-länd. A small Kaffir country in South Africa under British rule, bounded by Portuguese East Africa (Lourenço Marques), Natal (Tongaland), and the Transvaal Colony (Map: Transvaal Colony, H 5). Area, about 8500 square miles. The region is mountainous. The Lebombo chain lies on the east, the Drakensberg on the west. The general elevation is given as about 5000 feet. Swaziland is well watered, and is a fine grazing country. It is considered also well adapted for farming. There is much rich soil and the climate is healthful. The forests are large and valuable, possessing rare varieties of woods. Its gold deposits are now being mined. Copper, coal, and tin are said to exist. The British resident commissioner has his seat at Bremersdorp. The population is about 70,000, the Europeans numbering 1600. Swaziland became an independent State in 1843, its people having thrown off the yoke of the Zulus. In 1894, by convention between the Boers and British, the region came under the rule of the South African Republic (Transvaal), with whose downfall the sovereignty passed to Great Britain.

SWEARING, PROFANE. See BLASPHEMY.

SWEAT (AS. *swāt*, OHG. *sweiz*, Ger. *Schweiss*, sweat; connected with Lat. *sudor*, Gk. *ἱδρώς*, *hidrōs*, Lith. *swidrs*, Skt. *svēda*, sweat). The fluid that is excreted through the pores of the skin; perspiration. The nature, composition, and uses of this fluid in the normal state have been noticed in the article on SKIN (q.v.). The sweat is diminished in amount in many febrile diseases, especially if the temperature is high and prolonged. *Anidrosis*, as this condition is called, accompanies diseases in which there is a profuse discharge of fluid from the kidneys, as in diabetes, or from the bowels or stomach. In anasarca or general œdema and myxœdema sweat is diminished from stretching of the skin. Certain drugs, as belladonna and strychnine, markedly diminish the amount of sweat; others, notably pilocarpine, increase it. Profuse sweating (*hyperidrosis*) occurs in acute rheumatism, Asiatic cholera, and certain adynamic fevers, the sweating stage of malaria, the advanced stages of pulmonary phthisis, and septicæmia. Certain ailments are characterized by localized sweats; for example, the hands and feet in conditions of general debility; the head in rickets; and unilateral or one-sided sweating of the head or face or body in some nervous diseases, or from pressure on the sympathetic nerves by thoracic aneurism. The composition and color of the sweat may in rare instances undergo remarkable alterations. When through disease the action of the kidneys has become impaired the sweat has sometimes a urinous odor and deposits white scales or urinary solids upon the skin. This is known as *uridrosis*. *Bromidrosis* is an affection of the sweat glands characterized by offensive-smelling perspiration.

SWEATING SICKNESS. An extremely fatal epidemic disease which prevailed in Europe, and especially England, during the fifteenth, sixteenth, and early part of the seventeenth centuries. From the fact that the English people both at home and abroad were chiefly attacked, the malady was known as the 'English sweat' or 'English ephemera.' It first appeared in August, 1485, in the army of Henry VII. shortly after his arrival in Wales from France to fight the battle of Bosworth, and in a few weeks it had spread to London. It was a violent inflammatory fever, attacking as a rule robust, vigorous men, and characterized by a short chill, painful oppression over the epigastrium, headache, stupor, and a profuse fetid sweat. The disease took its course in about twenty-four hours. The patient suffered profound prostration and intense internal fever, but refrigerants seemed only to do harm. This epidemic lasted about a month, but during this short period many thousands died. The disease returned to England in 1506, 1517, 1528, and 1551. The epidemic of 1528 was particularly severe and was long referred to as 'the great mortality.' It raged over Europe—Germany, the Netherlands, Denmark, Sweden, Norway, Poland, Lithuania, and Livonia were all attacked.

In Hanover alone 8000 persons died. After 1551 no further epidemic occurred until the beginning of the eighteenth century. Since that time numerous outbreaks have been noted, but in a milder form. The disease is nearly always prevalent in some part of the world, most frequently in France (Picardy) and Italy, under the more modern name of *miliary fever*. (See MILIARIA.) In Germany it is still known as the 'English sweat.' As now observed, the disease is characterized by fever, profuse sweats, and an eruption of miliary vesicles. As in influenza a large number of people are attacked, but the epidemic lasts sometimes not more than seven or eight days, and the mortality is not high. For full historical accounts of the epidemics of the Middle Ages, consult Dr. Cains, *A Boke Against the Sweatyng Sicknesse* (1552); Hecker, *Epidemics of the Middle Ages* (*Sydenham Society Transactions*); Hirsch, *Geographical and Historical Pathology* (*new Sydenham Society Transactions*, vol. i.); and Creighton's *History of Epidemics in Britain* (1891).

SWEATING SYSTEM. The practice pursued by certain manufacturers, particularly of clothing, of giving out piece work to individuals on which the work is to be done at home and at starvation wages.

The system is a survival of the household form of industry that still exists in certain trades in large cities. The term 'sweater' was used first by journeymen tailors in London, who worked long hours. As more work was given out, the home worker employed his family and outsiders, and thus a system of sub-contract developed in which the middleman was called the sweater. To-day 'the sweating system' designates the fag end of all industries where low wages and bad conditions prevail. The work is on a cheap grade of goods, principally cigars, bread made in cellars, candy, and garments. The people sweated belong to a low class of unskilled labor, generally foreign born. The sub-contractors usually are Jews.

Evils of the sweat shop are long hours—ten to eighteen hours a day, including Sunday; overcrowding in the shops and surrounding tenements; unsanitary conditions in the work rooms and tenement houses, lacking in light, air, and cleanliness; child labor, very young girls and boys often running the machines; disease and deformity brought on by confinement and dust; irregularity of the work; and poor pay. The chief causes of the sweating system are (1) the excessive supply of unskilled labor; (2) an economic advantage to large dealers, in having their work done in small shops, thereby saving rent and evading factory laws, in cheap labor, in the inability of isolated workers to combine, and in the irregularity of work; (3) finally, the irresponsibility of employers, and the indifference of the public.

Among proposed remedies may be mentioned (1) stringent legislation, backed by public opinion, to force these kinds of work into large shops and factories; (2) coöperative production; (3) trade unions for unskilled workers; (4) public workshops; (5) restriction of foreign immigration; (6) an eight-hour day; (7) consumers' league. Factory laws of Ohio, Massachusetts, Illinois, and New York require licenses, or permits, for tenement houses, and also require the registering and describing rooms in which work may be done. Massachusetts only enforces such laws successfully; and she cannot protect herself against sweatshop goods from elsewhere.

See CONSUMERS' LEAGUE; LABOR PROBLEMS; FACTORIES AND THE FACTORY SYSTEM; FACTORY INSPECTION.

SWE'DEN (Sw. *Sverige*). The eastern and larger part of the Scandinavian peninsula. It is separated from Denmark on the southwest by the Cattegat and on the west, north, and east is bounded by Norway, Finland, and the Baltic Sea. It extends from latitude 55° 20′ N. to 69°, and from longitude 11° E. to 24°. Area, 172,876 square miles. In several physical aspects it differs much from Norway. It contains more level land and is more fertile and therefore adapted to support a larger population. Its coasts are not so deeply indented; its climate is continental instead of oceanic; and its harbors may be blocked with ice for five months, while those of Norway are unfrozen. Sweden comprises three main divisions. The northern half, which is very scantily inhabited, is called Norrland. The southern half comprises Svealand (Svearike), in the north, and Gotland (Götarike), in the south.

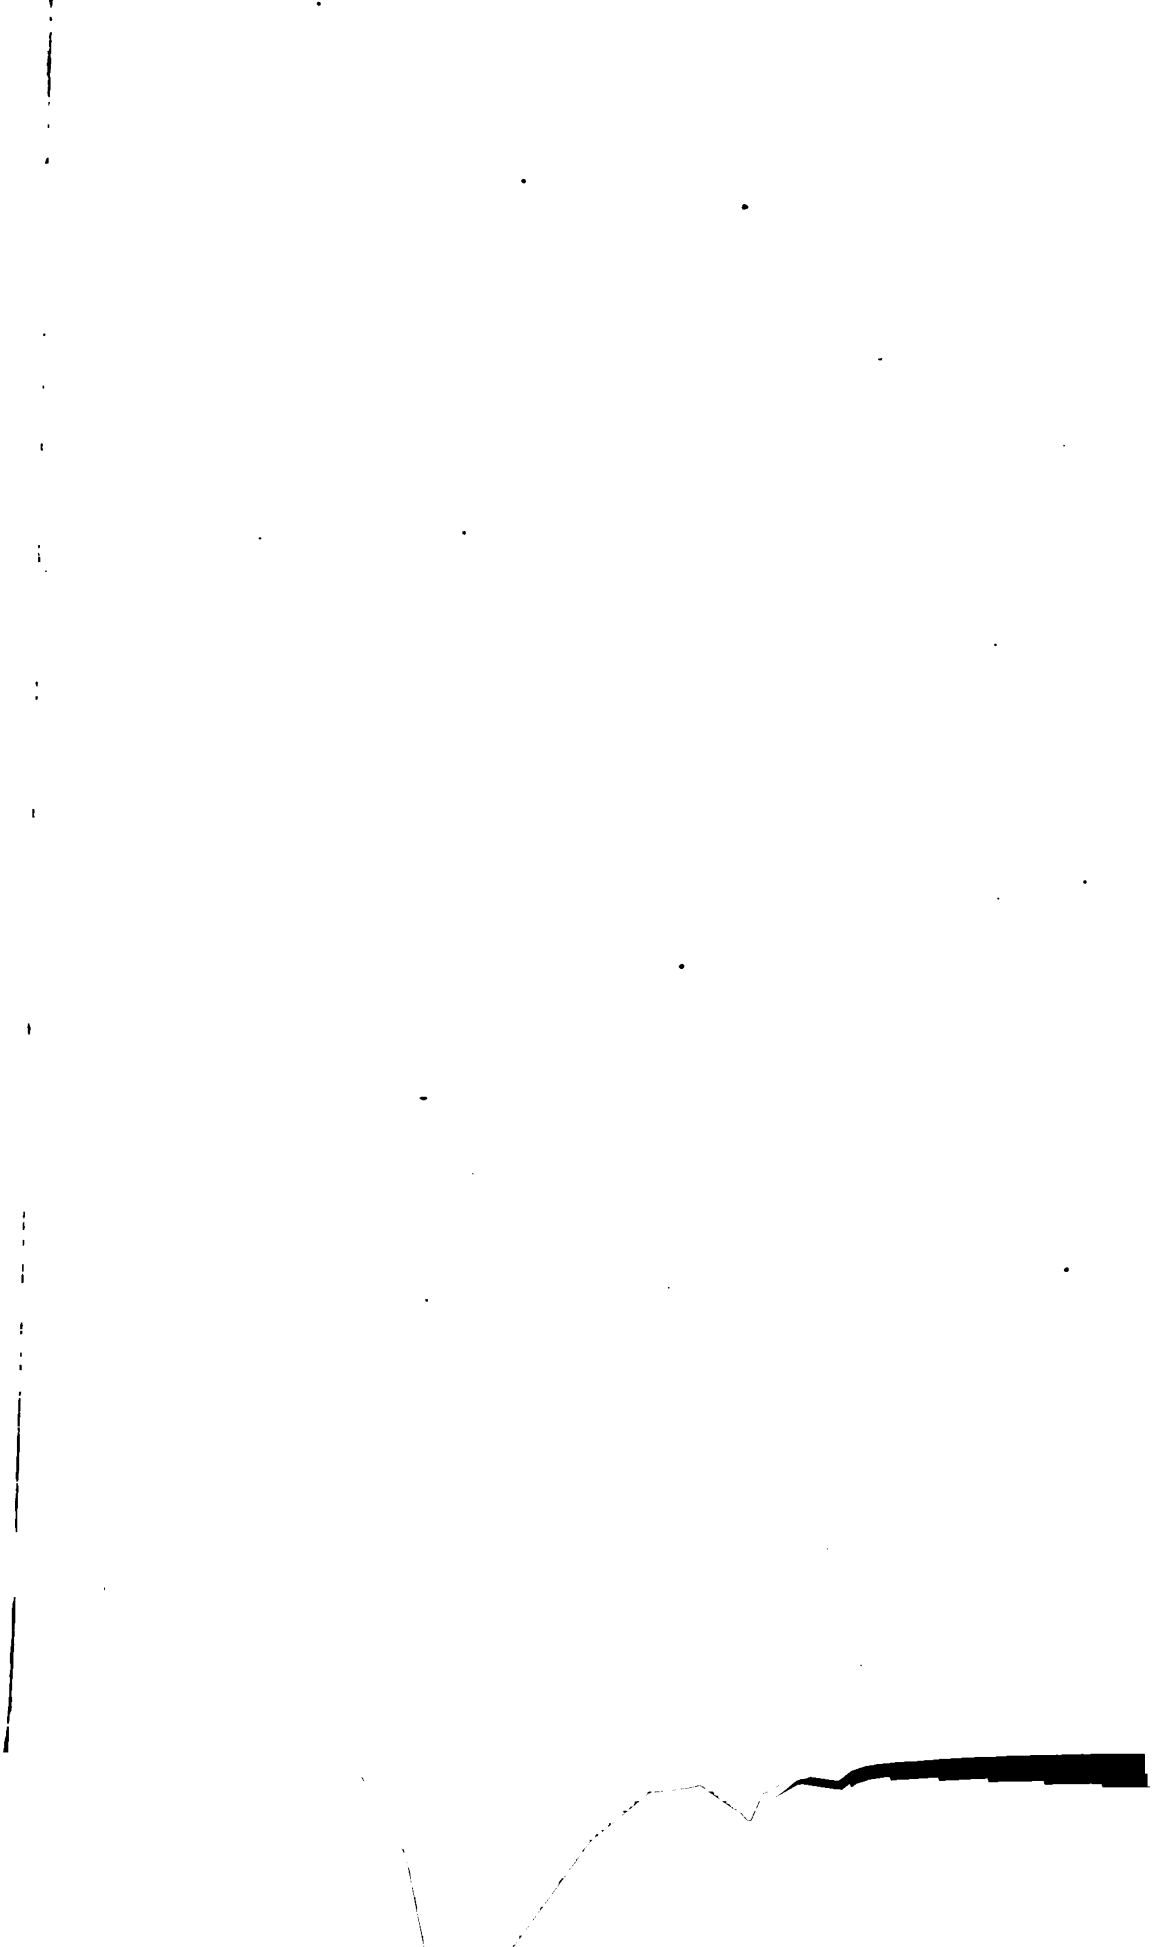
TOPOGRAPHY. The area of all the islands that are a part of Sweden is about 3000 square miles. A group of islands without mountains or vegetation skirt the Cattegat north of Göteborg; and north of Kalmar, on the Baltic side, are many islets, chiefly low rocks in shallow water, the continuation seaward of the Swedish plain. Two large islands in the Baltic lie off the southern or peninsular part of Sweden. The smaller, Öland, a narrow strip of land, 80 miles long, was once a part of the chalk shore of the mainland, from which it is separated by only two miles at the narrowest part of Kalmar Sound. The other, Gotland, is farther at sea, but connected with the mainland by a submarine bank. Only a comparatively small part of Sweden is very mountainous —the portion lying along the Norwegian border. The frontier region is not all mountains, but a part of it is a high and bleak plateau. (See *Topography* in NORWAY.) The greatest heights are in the northwest, Kebnekaisse being 7004 feet. In the south is a hilly district rising from a plateau that is several hundred feet above the surrounding plains of the coast, and is separated from the mountains of the north by the great depression occupied by the southern lakes. Most of the remainder of Sweden is a plateau sloping rapidly from the mountain fringe to a plain which stretches along the east coast to the southern extremity of the country, and which includes the fertile lowlands of Gotland, strewn with erratic boulders, where the largest and most productive farm lands are found.

HYDROGRAPHY. Sweden is well watered and is rich in lakes. Many rivers flow from the mountains southeast to the Gulf of Bothnia or the Baltic, affording much water power, but little navigation, on account of their rapid fall. They pass through many lakes, particu-

larly in the upper part of their courses, and the lakes have the effect of equalizing the floods so that the rivers are quite regular in their discharge. The numerous falls and rapids give picturesque charm to the rivers. The Klar Elf ('large stream'), the largest river, flows south into Lake Vener. The Göta Elf, which discharges the waters of Lake Vener into the Cattegat, is more important, because its falls and rapids have been circumvented by canals, making it a part of the waterway system of South Sweden. The principal river emptying into the Baltic is the Dal Elf. Many of the Swedish lakes are large and beautiful, and are distinguished by the clearness of their water and their picturesque surroundings. The four great lakes of the country lie in the depressed area north of the plateau of Southern Sweden. Lake Vener, the largest of them, is the third largest in Europe (over 2000 square miles). Lakes Vetter (about 700 square miles), Hjelmar, and Mälar (about 670 square miles) drain into the Baltic.

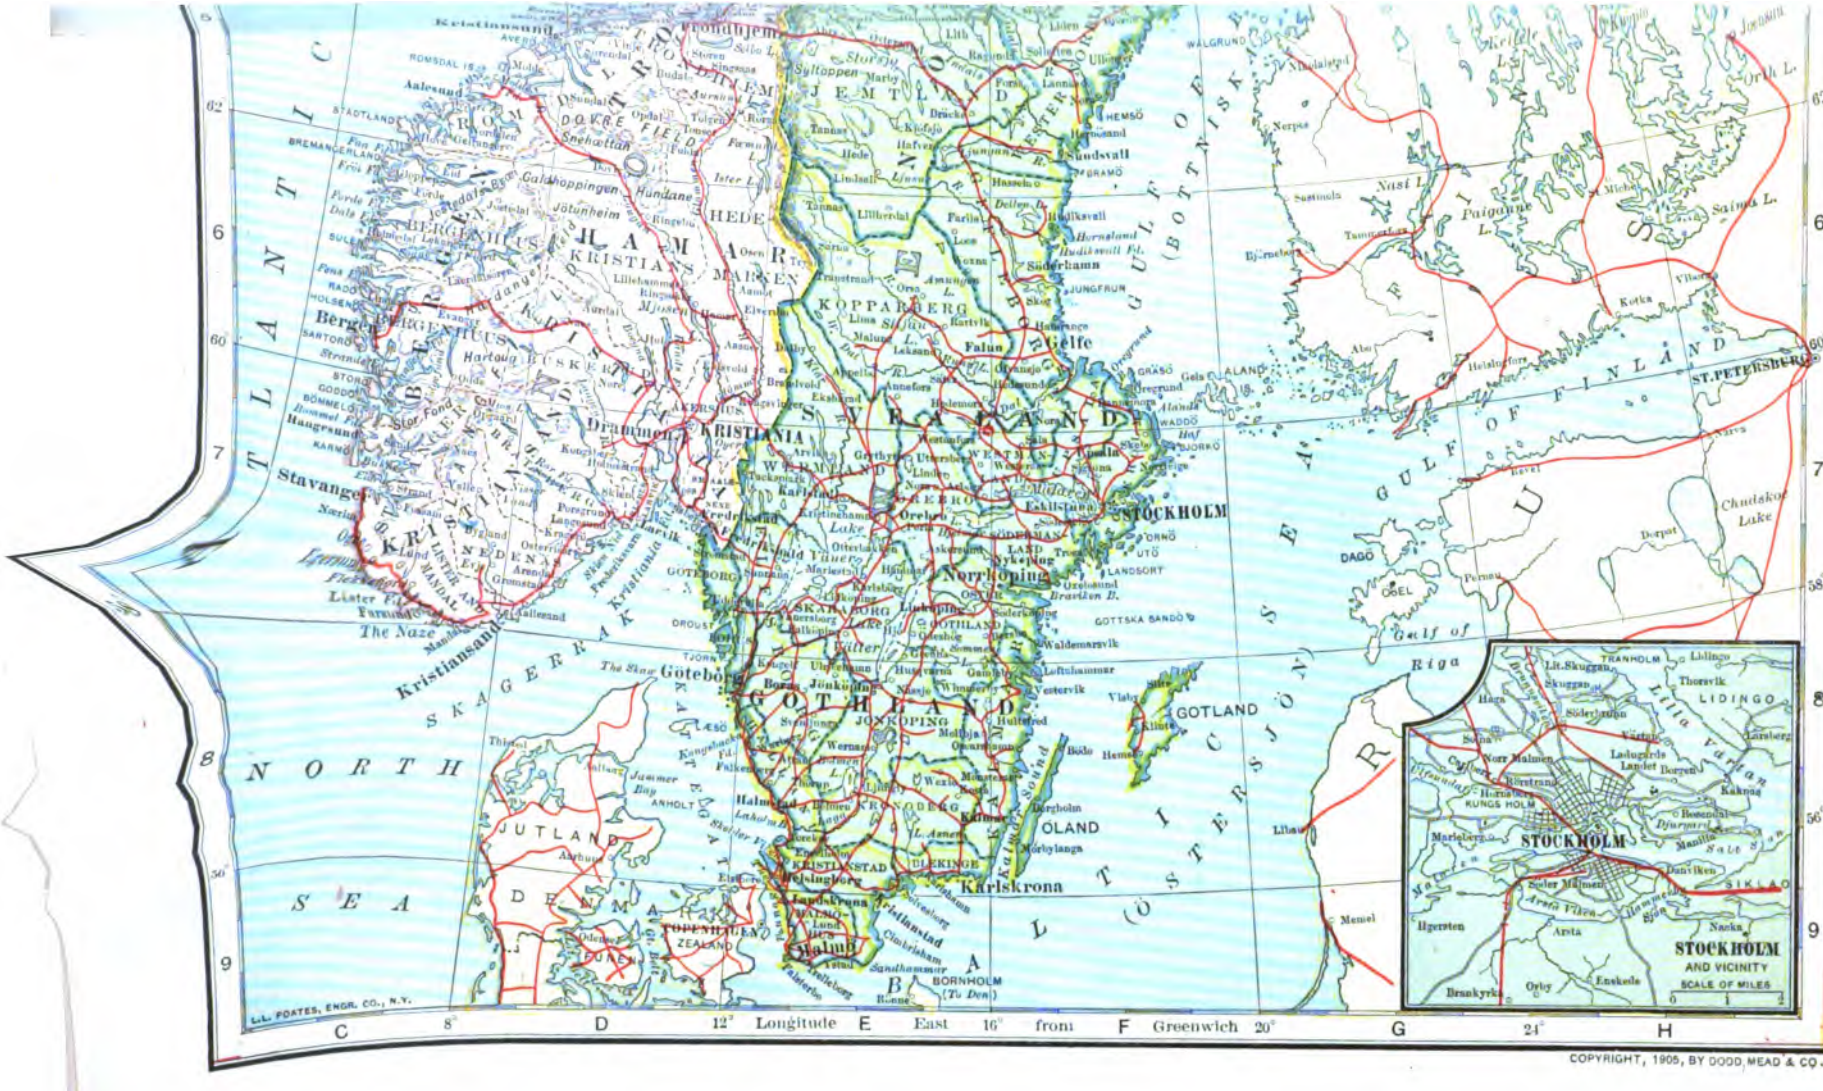
CLIMATE AND SOIL. As the western mountains shut off the tempering influence of the Atlantic, the climate is much colder than in Norway. The country being in the latitude of Labrador, the summer is short and the winter is cold and long. At Stockholm the mean temperature in January is about 25° F. and in July about 61°. The climate of Sweden is very healthy. The mountains prevent the greater part of the precipitation from reaching the eastern plateaus and plains, so that the mean rainfall in Sweden is only about 20 inches. The greatest rainfall is on the southwest coast, facing the Cattegat, where the average is 35 inches annually. The country is almost completely covered with snow in winter, when snow traveling on ski, or long wooden runners attached to the feet, is a favorite amusement. The splendid and extensive forests and the farms of Gotland and Scania, where the grain fields return as much to the acre as in England, show that the soils of the central and southern parts of the country are not deficient in fertility.

FLORA. Forests cover about two-fifths of the country, pines and firs predominating, and extend beyond the Arctic Circle. Over 2000 European plants have their northern limit in the Scandinavian peninsula. In Sweden beeches are found only in the extreme south, the oak disappears a little north of Stockholm, while the pine, fir, and alder extend nearly to the limit of arboreal vegetation. The forests of the southern plains differ little in appearance from those of the more temperate parts of Europe, but farther north, in the region of prevailing conifers, the labyrinth of moss-covered boulders, amid which the towering trees rise, where even a path is scarcely possible, gives a special character to the woodlands. The Dal Elf, north of Stockholm, is practically the northern limit of wheat, but barley is grown to the Arctic Circle.



FAUNA. The bounties paid for bear, lynx, wolf, and fox skins and for birds of prey have resulted in nearly exterminating the leading wild animals. The beaver and hare survive, but the wild reindeer is no longer found. Fish are much less abundant in Swedish than in Norwegian waters.

GEOLOGY AND MINERAL RESOURCES. Archæan rocks are predominant, and in some districts, especially around the great lakes, they are overlaid by Cambrian and Silurian formations. In large areas also the ancient rocks are covered by extensive glacial deposits of clay, sand, gravel, and erratic boulders. Triassic, Jurassic, and Cretaceous rocks appear only in Scania, in the extreme south. Some time after the glacial epoch the Scandinavian peninsula subsided till the sea level, in relation to the land, stood 500, 700, and in some places 1000 feet higher than before, as is shown by marine deposits resting on rocks that had been scarred by glacial ice. Then the land began to rise again and the gradual upheaval is still in progress. The movement is best observed, of course, along the coasts. It is nowhere so rapid as on the Swedish side of the Gulf of Bothnia, and it is most rapid at the northern extremity of the Gulf, where the upheaval is estimated at about 5 feet in the past century. In the extreme south no change of level has been observed. Thus the Gulf of Bothnia appears to be slowly draining into the southern basin of the Baltic.



The mining industry competes with difficulty against the powerful rivalry of the leading European countries, although it is more important than that of Norway. Sweden is poorly supplied with coal (only 271,509 tons having been mined in South Sweden in 1901). Manufacturers are compelled to import coal or use charcoal. The most important and valuable mineral product is iron. In 1901 2,793,566 tons of iron ore were mined in the kingdom. While about 1,000,000 tons are mined every year near Gefle, Falun, and Dannemora, the largest supply comes from Gellivare (q.v.), 130 miles north of the Arctic Circle. Swedish iron is regarded as unsurpassed in the world, as it is almost entirely free from phosphorus (.05 per cent. or less), and is therefore of superior value for the manufacture of steel. For this reason it now rivals the ores of Spain in British and German markets, and large quantities are exported. Magnetite and manganese ores (2271 tons of manganese in 1901) used in steel-making also abound. The copper industry of Falun was long widely renowned, but the yield was formerly much larger than at present (23,660 tons of ore in 1901). Three-fourths of the total yield of zinc ore (48,630 tons in 1901) is produced at the Ammeberg mines, on the north side of Lake Vetter. The silver product in 1901 was 1557 kilograms, and the yield of lead was 988,396 kilograms. The number of persons engaged in mining declined from 35,000 in 1890 to 30,776 in 1901.

AGRICULTURE, LIVE STOCK, AND FISHERIES. Three-fourths of the population support themselves by agriculture, though only about 8 per cent. of the land area is under cultivation. Hay meadows and pastures cover 4 per cent. of the surface, forests 44.2 per cent., and 43.6 per cent. is unproductive. In 1900, 388,416 farms were

	Area	Yield
Wheat	192,413	4,726,700

under cultivation, of which about two-thirds were from 5 to 45 acres in extent. The preceding table shows the area (in acres) under the chief crops in 1900 and the yield (in bushels).

The largest and most productive area of farm lands is in East and West Gotland and Scania, in the south of the country. In spite of the improvement in farming in recent years, especially through the importation of modern farm machinery and implements, the country cannot produce wheat and rye enough for home consumption, and about 12,000 tons of breadstuffs more than the kingdom produces are brought in every year, chiefly from the Baltic countries. Nearly half the total grain raised is oats, which is an export crop. The sugar beet thrives in the extreme south, but the acreage given to it is not sufficient to supply the demand for sugar. Flax, tobacco, and hops are cultivated with much success. At the end of 1900 Sweden had 533,050 horses, 2,582,555 head of cattle, 1,261,436 sheep, and 805,805 hogs. Great quantities of butter are exported to Great Britain. The Government has done much to improve agriculture by founding schools of agriculture and by the appointment of peripatetic teachers. The fisheries are important, though much inferior to those of Norway. They do not suffice for the needs of the country. On the other hand, the timber trade is of much greater value than that of Norway.

MANUFACTURES. Although the manufacturing industries have been stimulated in every way by the Government and have made great progress, Sweden is still largely dependent upon foreign countries for most of these commodities. The kingdom lacks the coal, population, and capital for the most successful development in this respect. The industrial advance, however, has been most substantial, as is seen from the following comparisons: From 1896 to the close of 1901 the number of manufacturing establishments increased from 8812 to 10,904; the workpeople in them from 202,293 to 262,229; and the total value of the product from $192,487,400 to $285,010,200. The sawmills in 1901 contributed 13.53 per cent. of the total value of product; flour mills, 7.70 per cent.; textile mills, 5.22 per cent.; machine shops, 5.14 per cent.; and iron and steel manufactures and foundries, 5.01 per cent. The timber industry in all its branches, including wood pulp, is the leading manufacturing industry. The public forests (area, 18,830,000 acres) yielded in 1899 timber valued at $20,085,650. In 1900 43,312 work people in 1148 saw and planing mills produced lumber worth $43,589,544; furniture and other woodwork were also large products. Swedish matches, everywhere famous, are produced chiefly at Jönköping, where one factory employs 1500 hands. There are woolen and cotton factories at Norrköping, Stockholm, and Göteborg, but the manufacture of linen, a household industry, is the only branch of textile manufacture which meets the domestic demand. The most famous iron works are near Eskilstuna and the chief machine shops at Motala. Swedish bar iron, steel goods, blades, armor plates, cables, nails, and knives are highly esteemed.

COMMERCE. The average annual trade (in million dollars) is as follows:

	1881-85	1891-95	1898	1900
Imports	85.5	97.5	122.0	143.3
Exports	67.5	88.5	92.4	104.8

The kingdom sells abroad the abundant product of its forests, iron and zinc mines, dairies, and oat fields. Its home supplies of textiles, wool, machinery, railroad iron, and many other things are inadequate, and it must supplement them by foreign purchases. The following table gives the value in kronor of the leading imports and exports for two years (a krona equals in value 26 7-10 cents):

	Imports 1899	Imports, 1900	Exports, 1899	Exports, 1900
	Kronor	Kronor	Kronor	Kronor
Textile manufactures	46,738,248	41,958,659	1,579,218	1,544,852
Grain and flour	49,327,777	51,793,392	4,850,060	2,145,094
Groceries	38,634,760	45,584,093	135,289	336,180
Raw textile material and yarn	47,818,471	46,165,793	1,252,671	1,502,842
Minerals, of imports mostly coal	82,388,362	104,052,262	21,421,309	22,518,863
Metal goods, machinery, etc	74,605,197	65,009,836	22,585,054	25,316,543
Live animals and animal food	23,542,296	29,195,718	48,128,649	43,161,578
Hair, hides, and other animal products	24,459,229	20,438,630	4,300,564	5,370,750
Metals, raw and partly wrought	13,159,371	25,556,124	43,513,013	52,395,087
Timber, wrought and unwrought	4,751,465	5,925,996	178,553,581	200,559,375
Paper and paper manufactures	4,745,770	4,407,698	11,706,764	14,392,265
Other articles	94,617,737	94,846,909	20,158,575	22,090,583
Total	504,788,683	534,935,110	358,184,767	391,333,962

The trade of Sweden is chiefly with the countries bordering on the Baltic and North Seas. The value of its trade in two years with the leading countries in its commerce was:

COUNTRY	Imports from (1899)	Imports from (1900)	Exports to (1899)	Exports to (1900)
	Kronor	Kronor	Kronor	Kronor
Great Britain	154,563,118	176,504,553	157,198,342	169,248,313
Germany	124,113,227	137,897,874	54,960,864	65,244,540
Denmark	60,681,189	62,525,129	43,298,276	47,682,183
Norway	20,449,964	21,761,911	6,451,052	7,186,593
Russia (including Finland)	28,502,181	34,358,984	15,861,424	14,027,846
France	8,992,214	9,692,566	29,065,568	29,807,333
Spain	1,767,701	1,736,294	2,851,295	3,649,832
Netherlands	10,390,719	11,184,942	25,686,540	29,941,211
Belgium	16,804,527	18,186,404	13,783,461	14,839,185

The exports of the United States to Sweden and Norway in 1899 were $10,000,000, and the imports were $4,000,000; in 1901 the exports to Sweden and Norway were $11,000,000 and the imports were $3,600,000. Among the things that the United States sells to these countries are provisions, wheat, machinery, tools, and cotton.

TRANSPORTATION AND COMMUNICATION. Railroads are cheaply built because of the small cost of land, lumber, and iron. Uninterrupted rail communication extends between Gellivare in the north and Malmö in the south, over 1200 miles. A line has been constructed from Gellivare to Ofoten Fiord, Norway, giving the iron ore of North Sweden an outlet on the Atlantic coast. The total length of railroads in 1900 was 7023 miles. Southern Sweden has an excellent system of waterways by which a series of canals and canalized rivers unite the great lakes with both the North and Baltic seas, providing about 2500 miles of interior navigation. In 1900, 100,806 ships and boats passed through the canals. Swedish trade, like that of Norway, is predominantly maritime, and Swedish vessels are engaged both in the home and foreign trade. The mercantile fleet in 1901 comprised 2987 vessels, of 613,792 tons, including 911 steamers, of 325,105 tons. Göteborg is the principal port, with Stockholm, Malmö, and Helsingborg following.

BANKING. The National Bank of Sweden (Riksbank) belongs to the State, regulates financial relations with foreign countries, receives private accounts, and lends money on security to non-speculative enterprises. The bank is under the guarantee of the Diet, its capital and reserve are fixed, and its note circulation is limited by its metallic stock and its current accounts. Its actual circulation is kept far within the authorized limit. The assets and liabilities of the Swedish banks balanced (in kronor) on January 1, 1902, as follows: National Bank, 245,255,457; private banks, 874,039,400; joint-stock banks, 581,424,650.

GOVERNMENT. Since 1814 Sweden has been united with Norway under a common king, but each is in effect a separate kingdom with its own government. The fundamental laws of Sweden have never been embodied in any single written constitution, but consist of various enactments of the Diet from 1809 to 1866. By the fundamental laws a limited monarchy is constituted, at the head of which is a king, who is required to be a member of the Lutheran Church and who is bound by oath to observe the laws of the land. By the law of succession women are excluded from the throne. In case of failure of succession the King is to be chosen by the Swedish and Norwegian Diets acting separately. The King has the exclusive right of legislation as regards trade, commerce, manufacturing, mines, and forests. He is also empowered to issue police regulations and to make rules concerning vagrancy, sanitation, protection against fire, etc. In legislating on other matters he must act with the consent of the Diet. He possesses the right to declare war and make peace upon the advice of a Council of State representing both monarchies. He nominates higher officials, military and civil, negotiates treaties with foreign countries, and presides in the Supreme Court. He is advised and in some manner assisted by a Council of State consisting at present of eleven Ministers, at the head of which is the Minister of State. They have seats in the Diet with the privilege of debate and the right to initiate legislation. They sometimes resign in case of serious disagreement with the Diet, but the principle of Ministerial responsibility is not yet freely recognized.

The National Parliament or Diet (Riksdag) consists of two Chambers, both of which are representative in principle. The Upper Chamber consists at present of 150 members chosen for a term of nine years by the provincial legislatures (*Landstings*), 25 in number, and by the municipal governments of those towns which are not represented in the provincial assemblies. These towns are Stockholm, Göteborg, Malmö, Norrköping, and Gefle. The members are distributed on the basis of one to every 30,000 of the population, and are required to be 35 years of age and in the possession for at least three years prior to their election of property of the taxable value of about $22,000, or an annual income of about $1100. They receive no compensation for their services. The Lower Chamber consists at present of 230 members chosen for a term of three years. Of these, 80 are chosen by the towns and 150 by the rural districts. The rural members are distributed on the basis of one member to every 40,000 inhabitants, while the towns are allowed one member for every 10,000 of the population. All native Swedes 21 years of age possessing property of the taxable value of about $280, or who cultivate for a period of five years a certain amount of land, or who pay an annual income tax on an income of about $225 are qualified voters. Any elector twenty-five years of age is qualified for membership in the Lower Chamber. The number of electors in 1899 was 339,876, less than 7 per cent. of the population, and but 40 per cent. of these actually voted. The members of the Second Chamber receive compensation.

The union of Norway and Sweden under the same executive makes necessary some provision for the administration of those affairs which are common to both monarchies, such as the conduct of their foreign relations. In this domain the King is given power to act for both countries, but his action is subject to the approval of the joint Council of State. Thus he may declare war and make peace, send and recall ambassadors, use ships of war, etc., with the consent of the joint council. This does not, however, destroy the individuality of either nation as regards foreign affairs, since the King may conclude treaties which affect but one of his kingdoms. Matters of common interest not within the power of the King are regulated by concurrent action of the two Diets. For the purposes of local administration Sweden is divided into 24 läns or provinces, each under the supervision of a prefect nominated by the King. In each province there is a general council or *Landsting*, which regulates internal affairs. The city of Stockholm, the capital, constitutes a separate administrative division. In the communes there is almost complete local self-government, all taxpayers being voters. Some of the communes have primary assemblies very much like the town meetings of New England, while those which are larger and more populous have municipal councils. In the parishes there are local assemblies for regulating ecclesiastical affairs.

FINANCE. The sources and amount of revenue and the expenditures for 1902 and 1903 were as follows:

REVENUE	1902	1903
	Kronor	Kronor
Domains, railways, land taxes, etc.	21,578,000	26,546,000
Customs	49,000,000	48,500,000
Post	12,400,000	13,340,000
Stamps	6,500,000	6,500,000
Impost on spirits, beet sugar, etc.	30,000,000	32,000,000
Tax on incomes, etc.	10,500,000	26,950,000
Net profit of the National Bank	2,000,000	2,716,200
Surplus from the previous years	24,165,000	15,916,000
Total revenue	156,143,000	172,468,200

EXPENDITURE	1902	1903
	Kronor	Kronor
(a) Ordinary:		
Royal household	1,321,000	1,321,000
Justice	3,852,420	3,911,815
Foreign affairs	652,050	659,150
Army	33,775,094	37,204,600
Navy	10,461,982	11,865,917
Interior	19,319,100	25,015,315
Education and ecclesiastical affairs	13,721,011	14,115,333
Finance	7,299,821	7,338,705
Agriculture	4,680,915	4,859,600
Pensions	3,649,115	3,786,632
	98,732,508	110,078,067
(b) Extraordinary	43,872,492	40,466,033
(c) Expenditure through the Riksgäldskontor:		
Payment of loans and miscellaneous (diet, etc.)	11,888,000	13,774,100
Carried to floating capital	.....	6,500,000
Fund for insurance against invalidity of workmen	1,400,000	1,400,000
Fund for insurance against accidents of workmen, etc.	250,000	250,000
Total expenditure	156,143,000	172,468,200

On January 1, 1902, the public liabilities, contracted entirely for railroads, were 349,132,333 kronor, bearing interest at from 3 to 4 per cent. All loans are paid off gradually by means of sinking funds.

WEIGHTS, MEASURES, AND MONEY. Gold is the standard of value. The krona, the unit of coinage, is worth 26 7-10 cents. The metric system of weights and measures became obligatory in 1889.

ARMY AND NAVY. See articles ARMIES and NAVIES.

POPULATION. The population, according to the census of 1901, was 5,175,228. The density of population is 30 to the square mile. The growth of population has been as follows: in 1800, 2,347,303; in 1840, 3,138,887; in 1870, 4,168,525; and in 1890, 4,784,981. The emigration, chiefly to America, has been large for many years, and since 1894 has varied from 8000 to 19,000 a year.

RELIGION. The Lutheran Protestant Church is recognized as the State religion, and most of the people are professors of that faith, its adherents numbering 4,735.218 in 1890. Other Protestants numbered 44,375 and there were a few followers of the Roman Catholic and other faiths. In the State Church are 12 bishoprics and 2572 parishes.

EDUCATION. Education is maintained at a high level. It is under the control of the Government, is compulsory, and practically all the inhabitants of school age and over can read and write. The secondary schools and the universities are modeled on the German system. In 1902 there were 1434 students in the University at Upsala and 644 in the University at Lund. The schools included in 1901: 79 public high schools, 18,085 pupils; 29 people's high schools, 1510 pupils; 14 normal schools for elementary teachers, 1325 pupils; 2 high and 6 elementary technical schools; 10 navigation schools, 729 pupils; and besides schools for deaf-mutes and the blind, medical, military, agricultural, veterinary, forestry, weaving, mining, and other special schools. In 1900 the expenditure on elementary education was 23,097,746 kronor, of which about one-fourth came from the national treasury.

ETHNOLOGY. The Swedes belong to the Scandinavian branch of the Teutonic stock. Their average stature is 1.705 meters, classing them among the tall races; the average cephalic index is 78.2. The Swedes are blondes, sturdy and robust. Prehistoric culture came from the South. In the settlement of Sweden the Goths or Gotar were the first conquerors of whom history tells. They occupied the southern parts, and following them came the Svear, who overran the rest of the country and gave their name to the Svenskar or Swedes of to-day. The Dalecarlians are thought to preserve best the type of the Svear; they are described as tall, slender, and agile, with blue eyes and broad, open brow, courteous, cheerful, and firm, and with a wide reputation for honesty.

HISTORY. Tacitus in the *Germania* tells of the two great Germanic tribes in the Scandinavian peninsula, the Suiones, or Swedes, in the north, and the Gothones, or Goths, in the south. These two, like other rival Germanic tribes, seem to have been generally at war with each other, and it was not until about the fourteenth century that the country was really organized and unified through the cessation of jealousy between the two sections. The ancient Swedish people had a bond of union in their religion and a common sanctuary at Upsala, which was the early centre of Swedish nationality. The history of Sweden previous to the tenth century is wrapped in obscurity. In the first half of the ninth century Ansgar (q.v.), a Frankish missionary, came to Sweden from Denmark, and began the teaching of Christianity, which slowly became established in the country. Under Eric the Saint (1150-60) the Swedish power was strengthened and extended and Christianity with it. Churches were built and monasteries founded. Eric carried Christianity into Finland with the sword and established Swedish settlements in that country, whose subjugation, however, was not completed

until more than a century after his death. He was defeated and killed in 1160 by the Danish prince Magnus Henriksen, who made an unprovoked attack upon Sweden, the beginning of a long series of wars between Sweden and Denmark, productive of national hatred and bitterness. The reigns of the early Swedish kings were short and stormy. In 1389 the Swedish nobles, disgusted with the conduct of their King, Albert of Mecklenburg, offered the crown to Margaret, Queen of Denmark and Norway, daughter of Valdemar IV., who defeated and dethroned Albert, and in 1397 brought about the union of Kalmar, by which the three Scandinavian kingdoms were henceforth to remain united under a single sovereign. This union continued with interruptions for more than a century, but with constant dissensions and wars between Denmark and the Swedish people. The Swedes themselves were divided between the upholders of national sovereignty and the supporters of the pretensions of the Danish kings. In the latter part of the fifteenth century the family of Sture (q.v.) rose to eminence in the struggle for national independence, Sten Sture, the Elder, being proclaimed administrator of the kingdom in 1470. In 1520 Christian II. of Denmark invaded Sweden to enforce his claim to sovereignty. The administrator, Sten Sture, the Younger, was defeated and mortally wounded and Christian entered Stockholm, where he enacted a carnival of blood, executing a large number of the nobles. Sweden soon rose against the tyrant (1521) under the lead of Gustavus Vasa, who was made administrator. He shook off the hated yoke of Denmark and in 1523 became King of Sweden. In 1529 Lutheranism was formally established as the State religion of the kingdom. Gustavus Vasa organized the kingdom as a hereditary monarchy, in which the power of the nobles was circumscribed and that of the clergy subordinated to that of the State. He fostered trade, manufactures, art, learning, and science, and left a full exchequer, a standing army, and a well-appointed navy.

The great work of the first Vasa sovereign was almost undone by his son and successor, Eric XIV. (1560-68), who became insane and was deposed, being succeeded by his brother, John III. At the beginning of Eric's reign Esthonia, a fragment of the dominions of the Knights Swordbearers, submitted to Sweden. The reign of John III. (1568-92) was notable for a reaction toward Catholicism. He had married Catharine Jagellon, of the Polish royal house, and in 1587 secured the election of his son Sigismund to the throne of Poland. For this Sigismund had to profess Catholicism. The great majority of the Swedes were strong Protestants, and when Sigismund succeeded his father as King of Sweden and attempted to restore Catholicism he was compelled by the Diet to resign the throne in 1599. His uncle Charles, the only one of Gustavus Vasa's sons who inherited his talents as a ruler, was made administrator of the kingdom and in 1604 was crowned King as Charles IX. The policy of Charles IX. was to encourage the burgher classes at the expense of the nobility; and by his successful efforts to foster trade—in furtherance of which he laid the foundations of Göteborg and other trading ports—to develop the mineral resources of the country, and to reorganize the system of Swedish jurisprudence, he did much to retrieve the calamitous errors of his predecessors. (See CHARLES IX.) The deposition of Sigismund gave rise to a long war with Poland. Charles was succeeded by his son, Gustavus II. Adolphus (1611-32). This greatest of Swedish kings was confronted at the beginning of his reign by wars with Russia, Poland, and Denmark, which last-named power still owned Scania and other districts at the southern extremity of the Scandinavian Peninsula. These wars were concluded advantageously for Sweden, which acquired Ingria, Karelia, and Livonia (the last-named not formally renounced by Poland until 1660), and the King addressed himself to the task of making Sweden the dominant power on the Baltic. In 1630 Gustavus Adolphus came to the rescue of German Protestantism, which had succumbed to the arms of Tilly and Wallenstein. (For his victorious career in Germany, and the successes of the generals who were trained in his school, see the articles GUSTAVUS II. ADOLPHUS, and THIRTY YEARS' WAR.) The foreign policy of Gustavus Adolphus was continued after his death at Lützen in 1632 by his able chancellor, Oxenstierna (q.v.), who directed the government during the minority of Gustavus's gifted but eccentric daughter Christina (1632-54). As a result Sweden was for nearly a century the great power of the north. By the Peace of Westphalia (1648) Sweden received Hither Pomerania (west of the Oder), the island of Rügen, and other territories in Germany, and was admitted to representation in the German Diet.

Charles X. Gustavus (1654-60) waged a fierce war against the Polish King, John Casimir, in which the Swedish forces overran Poland. He conquered from Denmark the provinces of Scania, Halland, and Blekinge, which rounded out the Swedish boundaries. The war with Poland was closed at his death by the Peace of Oliva (1660). Misgovernment by a regency followed during the minority of Charles X.'s son and successor, Charles XI. (q.v.) (1660-97). This King was involved as the ally of Louis XIV. in European wars, which the regency had not left him the resources to carry on. In 1675 the Swedes suffered a great defeat at the hands of Frederick William, the "Great Elector" of Brandenburg, at Fehrbellin. Charles XI. reorganized the government and was declared an absolute sovereign by the estates in 1693. His son, Charles XII. (1697-1718), by his military genius raised Sweden to an extraordinary pitch of power. Not long after his accession he successfully met a joint attack by Russia, Poland, and Denmark, dealing blows that astonished the world. His inordinate ambition, however, finally brought ruin upon Sweden. Peter the Great wrested from her Karelia, Ingria, Esthonia, and Livonia. Charles met his death in an invasion of Norway, leaving the kingdom overwhelmed with debts and again disorganized. With him the male line of the House of Vasa expired. His sister Ulrica Eleonora, who succeeded him, and her husband, Frederick of Hesse-Cassel, who shared the throne, were mere puppets of the nobles, whose dissensions as the factions of the 'Hats,' or French party, and the 'Caps,' or Russian party, brought on the country calamitous wars and almost equally disastrous treaties of peace. The weak

Adolphus Frederick of Holstein-Gottorp, who was called to the throne on the death of Frederick in 1751 and died in 1771, did little to retrieve the evil fortunes of the State. (See STRUENSEE.) His son, Gustavus III. (q.v.) (1771-92), skillfully availed himself of the general dissatisfaction of the people with the nobles, to destroy the factions of the Hats and Caps, and under a new constitution to restore the power of the Crown and of the popular estates at the expense of the nobles. His extravagance and dissoluteness detracted, however, from his merits as a ruler. He was assassinated in 1792. His son and successor, Gustavus IV. Adolphus (q.v.), was but three years of age at his accession, and was forcibly deposed in 1809, and obliged to renounce the crown for himself and his direct heirs in favor of his uncle, Charles XIII. (1809-18), who was compelled at once to conclude a humiliating peace with Russia, by the terms of which Finland was severed from Sweden. The early part of the reign of Charles, who was childless, was troubled by domestic and foreign intrigues to regulate the choice of an heir to the throne. Finally, hoping to conciliate Napoleon, the dominant party in Sweden elected General Bernadotte to the rank of Crown Prince. Bernadotte led the Swedish forces in support of the Allies against the French Emperor in 1813-14. With the aid of England, Sweden compelled Denmark, in January, 1814, to cede Norway to her, the Swedish possessions in Pomerania being handed over to Denmark. The Congress of Vienna (1814-15) recognized the union of Norway with Sweden; Swedish Pomerania passed to Prussia. In 1818 Bernadotte mounted the throne as Charles XIV. John (q.v.). Under his able administration the united kingdoms of Sweden and Norway made great advances in material prosperity and political and intellectual progress; and although the nation at large entertained very little personal regard for their alien sovereign, his son and successor, Oscar I. (1844-59), and his grandsons, Charles XV. and the present King, Oscar II., who came to the throne in 1872, won a large share of the affections of the Swedes. The great problem of the dual kingdom under the present sovereign has been to satisfy the demands of the Norwegians, who are more democratic than the Swedes and are restive under the union. See NORWAY.

SWE'DENBORG, *Sw. pron.* svā'den-bŏry', EMANUEL (1688-1772). A Swedish scientist and theologian. He was born in Stockholm and died in London. His father was Jesper Svedberg, subsequently Bishop of Skara. He was educated at Upsala, and traveled for four years in England, Holland, France, and Germany. On his return to Sweden he was appointed by Charles XII. to an assessorship of mines. Swedenborg was ennobled in 1719, and the family name changed from Svedberg to Swedenborg. Swedenborg published short treatises on various topics in the fields of mathematics, astronomy, physics, and chemistry. He devoted himself for eleven years to the duties of his assessorship and to a systematic description of mining and smelting, and the construction of a theory of the origin of creation. The result appeared at Leipzig in 1734, in three massive folios, entitled *Opera Philosophica et Mineralia*. This was followed in the same year by a treatise on *The Infinite, and the Final Cause of Creation; and the Mechanism of the Operation of the Soul and the Body*, carrying the doctrine of the *Principia* into higher regions. Dissatisfied with his conclusions, he determined to track the soul to its inmost recesses in the body. His studies in human anatomy and physiology, with this end in view, appeared as *Œconomia Regni Animalis*, in two volumes, 1741, and as *Regnum Animale*, in three volumes, unfinished, 1744-45.

At this point his course as scientist was arrested, and he entered on his career as seer, by which he is known in history. After 1745 he professed to have had his spiritual senses opened. His recorded experience was unique in this respect, that it did not consist in having communication with spirits, as is the claim in modern spiritualism; nor did it consist in having visions merely, and receiving communications, as was the case with the prophets; but it consisted in being himself consciously an inhabitant of the spiritual world as if he had died, and thence in associating with the people of that world as one of them. In 1749 he made his first public appearance in his new character in the issue in London of the *Arcana Cœlestia*, completed in 1756 in eight quartos. It is a revelation of the internal, or spiritual, sense of Genesis and Exodus. Adam signifies the Most Ancient Church, and the flood its dissolution; Noah, the Ancient Church, which, falling into idolatry, was superseded by the Jewish. The spiritual sense pervades the Scriptures, with the exception of Ruth, Chronicles, Ezra, Nehemiah, Esther, Job, Proverbs, Ecclesiastes, the Song of Solomon, the Acts of the Apostles, and the Epistles. By reason of its symbolism of the inward sense, the letter of Scripture is holy in every jot and tittle,

and has been preserved in immaculate perfection since the hour of its divine dictation. The Jewish dispensation having reached its period, God appeared in Jesus Christ. He assumed human nature in its lowest condition in the Virgin, wrought it into conformity with himself, "glorified and made it divine." There is a Trinity, not of Persons, but of Divine Essentials, consisting of the Father, or God as He is in himself, and thus incomprehensible to man; the Son, or God as revealed to man in Jesus Christ; and the Holy Spirit, or divine operation thence. It is imaged in man by his soul, his body, and their operation. Swedenborg acknowledged God in Jesus Christ, and regarded Him as the sole object of Christian worship. The Church which Christ established at His advent in the flesh came to an end in 1757, and Swedenborg witnessed the last General Judgment at that time effected in the world of spirits. Then commenced a new dispensation, and a New Church, signified by the New Jerusalem in the Revelation, of which the writings of Swedenborg contained the doctrines.

The grand and distinctive principle of Swedenborgian theology, next to the doctrine of the divine humanity, is the doctrine of life. God alone lives. Creation is dead—man is dead; and their apparent life is the divine presence. God is everywhere the same. It fallaciously appears as if He were different in one man and in another. The difference is in the recipients; by one He is not received in the same degree as another. There is an inmost, or highest, degree, or plane, of man's reception of the divine life, called the celestial or love plane; there is a second, or lower degree of receptivity called the spiritual or wisdom plane, and there is a third called the natural or plane of obedience. The life of evil is the perversion of divine life into disorderly forms. These degrees of man's reception of God's life are entirely separate from each other, and can never be commingled. They are related by correspondence, by which each lower degree derives its existence and its life from the plane above. The relation of correspondence is plenary, there being nothing in a higher plane which is not represented by something corresponding to it in the plane below; and there is nothing in the lower plane which does not exist from some corresponding thing in the plane above; and all this to the most minute detail, even to the things on this earth. Earthly things beautiful and useful manifest spiritual good; and earthly things ugly and hurtful, spiritual evil. The Scriptures are written according to correspondences, and by the aid of that science their mysteries are unlocked. By it, too, the constitution of heaven and of hell is revealed. There are three heavens in which there live three orders of angels, the first, the second, and the third, or the natural, the spiritual, and the celestial; they are three planes, or degrees, of man's receptivity of divine life described above. All angels were once men, and have lived on this or some other planet. They marry and live in societies, in cities and countries as in the world, in outer appearance differing only in the vast superiority and glory of these things there. But the similarity between the life of angels in heaven and that of men on earth is of the outer appearance only, while the differences between them are internal and radical; for it is not in degrees of outer perfection and glory that the life in heaven and the life on earth may be compared truly, but in their capacity to supply a field for the realization of the inner life of the soul. To the angels the images presented to their senses are the expressions of ideas and emotions which are by this means revealed to them; and so concerned are they in these meanings, that they are unconscious of the objects of their senses, or of their own bodily life, as such. To them their sense-life therefore is made only a visible, audible, and tangible—a concrete spiritual life. There is no denominational favoritism with God; all in whom the love for God and man prevails in any degree whatever, and whatever may have been their Church, or religious connection, go to heaven after the death of their bodies. Between heaven and hell, there is an intermediate state called the world of spirits, where all those who pass into the spiritual world are prepared for their final states. Hell is not merely a place of punishment for the sins done in the body, but is a provision of divine love, and the necessary state and condition of the unregenerated natural man. No one is sent there, but the unregenerated seek a place there of their own accord. Hell as a whole is called the devil, or Satan; there is no supreme individual bearing that name. There are three hells opposite the three heavens.

All of Swedenborg's works were written in Latin and received little attention from contemporaries. The American Swedenborg Printing and Publishing Society of New York issued complete editions of the theological works in English, a nearly complete edition in Latin, certain of the works in Latin-English, and some in other languages. Most of the original manuscripts have been reproduced by photolithographic processes. Complete editions have been issued in English by the Swedenborg Society of London, which has also issued a concordance to the works by Potts (6 vols. 1888 et seq.). The *Rotch Edition* of Swedenborg's works in small volume is published by the Massachusetts New-Church Union. About forty biographies of Swedenborg have been published. The most important of those now in print are by Wilkinson (London, 1849), White (ib., 1856), Swift (ib., 1883), and Worcester (Boston, 1883). Consult also *Documents Concerning the Life and Character of Emanuel Swedenborg, Collected, Translated, and Annotated* by R. L. Tafel (London, 1875-77), a very scholarly work, compiled with great labor.

SWEDENBORGIANS. The name popularly applied to those who accept the doctrines of Christianity and of philosophy as set forth in the writings of Emanuel Swedenborg (q.v.). They do not call themselves Swedenborgians, but members of the New Church. Swedenborg formed no ecclesiastical organization, and many of his followers do not sever themselves from their previous Church connections; but the majority have organized a Church which they have named 'The Church of the New Jerusalem,' after the New Jerusalem of Apocalyptic vision (Rev. xxi.). The first movement toward organization began in Great Britain in 1782, when Robert Hindmarsh, a printer of London, and certain associates formed a class for reading and studying

the writings of Swedenborg. This grew into a society for worship and preaching. Public services were first held in 1788. The General Conference of the New Jerusalem Church in that country began its sessions in 1789, and since 1815 has met annually. In 1902 the Conference consisted of 73 societies, with an aggregate membership of 6337. There were twelve societies, with a membership of 193, which do not belong to the Conference, and also 996 believers not connected with any society, enrolled as 'isolated receivers,' making a grand total of 7526 enrolled Swedenborgians in Great Britain. On the Continent of Europe there is a society of Swedenborgians in each of the cities of Paris, Zurich, Florence, Budapest, Vienna, Stuttgart, Copenhagen, Stockholm, and Gothenburg. In the United States the first society of Swedenborgians was organized in Baltimore in 1792. The General Convention of the New Jerusalem in the United States and Canada held its first meeting in Philadelphia in 1817. With little interruption this body has held annual sessions ever since. In this country the Swedenborgian societies are grouped into State organizations, called associations. The General Convention is composed of twelve of these associations, and of nine separate societies. The individual membership of the bodies composing the Convention as reported in 1902 was 6812. There is a smaller organization of the Swedenborgians called *The General Church of the New Jerusalem*. Its headquarters are in the United States, though it has members in other countries. It is an offshoot from the Convention, having withdrawn from that body in 1891. It reports a membership of 600. In Australia there are four societies of Swedenborgians, with an aggregate membership of about 350; and there is a society in New Zealand; one on the island of Mauritius, in the Indian Ocean; and one at Durban, South Africa. There are also circles of readers and students of Swedenborg of sufficient importance to be reported in the journals of the organization in British India, China, Japan, and South America. Taken all together there are not far from 16,000 registered adult members of the Swedenborgian faith in the world.

The ministry of the Swedenborgians is patterned after the Episcopal order. In the General Conference of Great Britain there are 7 ordaining ministers, 35 ordained ministers, and 12 recognized leaders and missionaries, making a total ministerial force of 54. In the General Convention of the United States there are 6 general pastors, 102 pastors and ministers, and 16 authorized candidates and preachers, making a total of 124 in its ministerial force. The General Church of the New Jerusalem reports one bishop, 16 pastors, 4 ministers, and 2 candidates, making a ministerial force of 23. The pastors and ministers of the societies scattered throughout the world for the most part act under the authority of some one of these three general bodies, and their ministerial force of about 200 as reported above may be considered as constituting the entire clergy of the Swedenborgians in the world. In this classification the ordaining ministers of the General Conference, the general pastors of the General Convention, and the bishop of the General Church hold among Swedenborgians a position similar to that of a bishop of the Episcopal Church, though with the exception of the bishop of the General Church they do not exercise such authority.

A number of Swedenborgian societies in England conduct secular schools in connection with their religious societies. There are ten such institutions, with an aggregate enrollment (in 1902) of 4375 scholars. There is also a New Church College, London, concerned for the most part in preparing young men for the ministry. In the United States there are The Waltham New Church School, at Waltham, Mass.; The Urbana University, at Urbana, Ohio; The New Church Theological School, at Cambridge, Mass.; and The Academy of the New Church, at Bryn Athyn, Pa., conducted by the General Church, which has also several parochial schools in the United States and Canada. The sect publishes many journals.

SWEDISH LANGUAGE AND LITERATURE. Swedish belongs to the northern branch of the Germanic family, within which it is an eastern development of the old *donsk tunga*, or Danish tongue, a name anciently applied to the language spoken not in Denmark only, but in the rest of Scandinavia as well. It was very much the same in the entire Northland down to about A.D. 900, or a little later, when it began to differentiate into an eastern type, ramifying into Danish and Swedish, and a western type, giving rise to Norwegian and Icelandic. From 900 to 1500 the Swedish branch is called Old Swedish. Until after 1200 the only records are runic inscriptions, cut for the most part on gravestones. The use of the Latin alphabet began in the thirteenth century. In the fourteenth century, when a literary language began to develop out of the Södermanland dialect, the differentiation from Danish proceeded slowly; after this came a period of extensive approximation to Danish, to be followed in time by an archaizing period, which restored original forms. Aside from divergencies of vocabulary, Swedish now differs from Danish especially in its retention, after a vowel, of the old voiceless consonants, *k*, *t*, *p*, which in Danish changed to *g*, *d*, *b*, and in its retention of the vowels *a* and *o* in unstressed syllables, where Danish has *e* or no vowel at all; thus Swedish *bok*, 'book,' *mat*, 'meat,' *apa*, 'ape,' are in Danish *bog*, *mad*, *abe*. Swedish *talar ni svenska* 'do you speak Swedish?' is in Danish *taler de svensk;* and Swedish *flickan liknar sin mor*, 'the girl resembles her mother,' is in Danish *pigen ligner moderen*. Under this head it may be added that Swedish has not the 'glottal catch' of Danish, and that Danish has not the delicately modulated musical accent of Swedish.

The main body of the Swedish vocabulary is old Germanic stock, the principal foreign ingredients being (1) Latin and Greek words that came in with Christianity or with the growth of scholarship; (2) Low German words dating from the time of the Hanseatic League, as *arbeta*, 'to work,' *stövel*, 'boot,' *smaka*, 'taste;' (3) German words from the time of the Thirty Years' War, as *tapper*, 'brave,' *prakt*, 'splendor;' (4) French words borrowed in the seventeenth and eighteenth centuries, as *affär*, 'business.' *talang*, 'talent,' *charmant*, 'charming.' Like the other North-Germanic tongues, Swedish has the postpositive definite article (originally a pronominal

affix); thus *flicka*, 'girl,' *flickan*, 'the girl.' As in English, nouns have but one case (the genitive), which is now distinguished by inflection. The genitive ending is *-s*, which is appended after the article; thus *flickans mor*, 'the girl's mother.' The plural of nouns is formed by means of the endings *-or*, *-ar*, *-er*, *-en*, to which the definite article is appended in the forms *-na*, *-ne*, according to a feeling for vowel-balance which shows itself as early as the fourteenth century; thus *flickorna*, 'the girls,' but *dalarne*, 'the dales.' A new pronoun of address, *ni*, taking the place of *I*, came into the language in the seventeenth century and is now commonly used in books; but in conversation Swedish politeness prefers to avoid it and substitute the title of the person addressed, putting the verb in the third person; thus, *är frun sjuk*, 'is the lady sick?' = 'are you sick, madam?' The verb still retains the old Scandinavian passive in *-s*, which was originally an affixed reflexive pronoun; thus, *kalla*, 'call,' *kallas*, 'to be called.' A more peculiar feature of conjugation is the differentiation of the perfect passive participle into two forms, one of which, called the supine, is used to inflect the perfect tenses, while the other is declinable and serves as a true participle; thus *jag har älskat*, 'I have loved,' but *jag är alskad*, 'I am loved,' and *vi äro älskade*, 'we are loved.'

In the printing of Swedish the Roman letters have long since prevailed. Speaking somewhat roughly, the written language of to-day represents the pronunciation of about two hundred years ago; and as phonetic change has been at work during the interval, it is the case, just as in English, that the written form is often a bad index to colloquial utterance. Swedish print teems with 'silent' letters; thus, *jag skal vara i staden*, 'I shall be in the city,' is pronounced *ja ska vara i stän;* and *hvad är det*, 'what is it?' becomes *va ä de*. For the learner of Swedish one of the greatest difficulties is presented by its peculiar accent, which involves both stress and variations of musical pitch. Every word has either the simple or the compound tone. The simple tone is a rising modulation, while the compound (to quote from Sweet) "consists of a falling tone on the stress-syllable, with an upward leap of the voice and a slight secondary stress on a succeeding syllable." Not only the correct pronunciation, but the very meaning of a word often depends on the exact modulation of its musical accent.

BIBLIOGRAPHY. For Old Swedish the leading authority is Noreen, *Altschwedische Grammatik* (Halle, 1897). He has also treated the subject in his *Geschichte der nordischen Sprachen* (Strassburg, 1898), a reprint of his article in the second edition of Paul's *Grundriss*. The great work on Swedish grammar is Rydqvist, *Svenska sprdkets lagar* (6 vols., Stockholm, 1850-83). A good small grammar is Schwarz and Noreen's *Svensk sprdklara* (ib., 1881). There is no good grammar in English. The best Swedish-English dictionary is that of Björkman (Stockholm, 1886). The great dictionary of the Swedish Academy, *Ordbook öfver svenska spräket* (Lund, 1894 et seq.), is only in the initial stages. On the subject of the dialects consult Lundell, *Nyare bidrag till kännedom om de svenska landsmalen*, etc. (Stockholm, 1879 et seq.). An excellent account of Swedish pronunciation by Sweet is given in *Transactions of the Philological Society* (London, 1877-79).

THE LITERATURE. About 160 of the runic inscriptions of Sweden, the oldest dating from the tenth century, contain alliterating verses evidently quoted from preëxisting sagas. This and other lines of evidence show that the poetic art was widely cultivated in the Viking Age. But this 'literature,' which may have been comparable to that preserved in Old Icelandic, is lost. By the middle of the twelfth century Christianity was firmly established, and the old pagan songs and sagas fell under the ban of the Church. From that time on for five hundred years the national literature was dominated, rather more than elsewhere in Western Europe, by the religious spirit. The earliest writings that have come down in the Latin alphabet are certain codes of provincial laws (*landskapslagar*). The most important is the "Elder West Göta Law," dating from the thirteenth century. Magnus Eriksson's *Landslag* (about 1350) is that King's attempt to provide a common law for all the provinces he had brought under his rule. It was probably a scholar from the entourage of this same King Magnus who wrote the celebrated *Um styrilsi konunga ok höfþinga* ("On the Conduct of Kings and Magnates"). To the fourteenth century belong the writings ascribed to Saint Birgitta, a pious nun and mystic revealer of heavenly things. There are nine books of her "Revelations." Saint Birgitta is the most eminent personage in the annals of Catholic Sweden. She made the Convent of Vadstena a literary centre, where many Latin writings, chiefly mystical and hagiographic, but including a part of the Bible, were translated into Swedish for the benefit of the nuns. In poetry the mediæval period is not very rich, though its aggregate of metrical production is considerable. The romances of chivalry are represented in the so-called *Eufemiavisor*, certain tales of knighthood done into Swedish verse by a gleeman living at the court of Queen Euphemia of Norway (1303-12). They are *Herra Iwan*, *Hertig Fredrik af Normandie*, and *Flores och Blanzaflor*, *all* in rhyming couplets with four accents to the line. Besides these metrical romances, there are several rhymed chronicles, the oldest being the *Erikskrönika* (about 1320), and the ballads. It is agreed that the ballad-making period in Sweden was in the thirteenth and fourteenth centuries, but the extant collections are of the sixteenth and seventeenth. None of the known specimens are of indisputable antiquity, but the best compare very well in form and matter with the better *Kæmpeviser* of Denmark. From the fifteenth century we have a few good poems by Bishop Thomas of Strengnäs (died in 1443).

The Reformation transferred the literary centre from Vadstena to Upsala. The literature of the sixteenth century is almost exclusively religious, the two chief writers being the brothers Petri, Carmelite monks who had been converted to Lutheranism at Wittenberg. They stand out as the leading Swedish apostles of the new faith. The elder, Olavus ('Master Olof'), wrote psalms, devotional poems, a prose chronicle of Swedish history, and (probably) the mystery-play *Tobie Comedia*. With his brother Laurentius he directed the publication of the first Swedish Bible

(Upsala, 1541). The first secular author of any note in the new era is the historian Messenius, who also wrote six 'school comedies' on subjects from Swedish history. The best known is *Disa*, which was played by Upsala students in 1611.

The period of Swedish expansion (1630-1730) is marked by the widening of the literary horizon through the introduction of new ideas and forms from Germany, France, Italy, and Holland. The prominent figure is Stjernhjelm (1598-1672), the 'father of Swedish poetry.' He did a work like that of Opitz in Germany, by whom he was influenced; that is, he sought to give his country a worthy poetic literature by imitating good models, old and new. He laid great stress on metrical regularity and ornateness of diction. His poem *Hercules*, a didactic allegory on the conflict of Pleasure and Duty, may fairly be said to have nationalized the dactylic hexameter. It is metrically elegant, but rather florid. Stjernhjelm also experimented with alexandrines, the *ottava rima*, the sonnet, and the ballad. His most noteworthy disciple was the poet-scholar Columbus (1642-79). An opponent of Stjernhjelm, Rosenhane (1619-84), won fame especially as a sonneteer. A jovial and facile rhymester who stood apart from the schools was Johansson, called Lucidor (died in 1684). The eccentric polyhistor Rudbeck (1630-1702), with his amazing *Atlantika*, belongs to the history of literary curiosities rather than of literature.

In the ensuing epoch (1730-1772) the great Swedish names are Swedenborg and Linnæus; but they belong, respectively, to the history of religion and of science. In belles lettres the ideals of Sweden were substantially those of contemporary France and England. The presiding genius is Dalin (1708-63), whose *Swedish Argus*, started in 1732 in imitation of the *Spectator*, became the rallying-point of the dominant ideas. Dalin had something of Voltaire's versatility and cleverness. He wrote much poetry, but is best remembered as an elegant stylist in prose, the first in Swedish annals. Opposed to Dalin in some of his tendencies was the coterie of Fru Nordenflycht (1718-63), the 'Northern Aspasia.' Her salon in Stockholm was not unworthy of its Parisian models. To her circle belonged Creutz (1729-85), best known for his pleasant pastoral *Atis och Camilla*, and Gyllenborg (1731-1808), author of many ratiocinative poems. All these mid-century writers were strongly influenced by their contemporaries in England.

The Gustavian epoch (1772-1809) is marked by royal patronage of letters on a large scale. Gustavus III., himself a playwright and a prize orator, assembled an academic court of talent, which continued the French tradition of the Old Régime. The leading Gustavians were Kellgren (1751-95), Leopold (1756-1829), and Oxenstjerna (1750-1818), all poets of considerable talent and devoted to the ideals and sentiments of the expiring Age of Enlightenment. Here belongs also the name of the gifted poetess Fru Lenngren (1754-1817), famed for her idyls and satires and her literary salon. Quite untouched by academic influence was the much admired Bellman (1740-95), a genial humorist of Anacreontic tendencies, who turned his observations of Stockholm low life into tuneful verse. To the Gustavian period finally, though not of its spirit and distinctly prophetic of a new era, the best work of the eminent lyric poet Franzén (1772-1847).

The great Romantic movement of the nineteenth century, with the concomitant renaissance of national feeling, affected Swedish literature profoundly. The new ideas, coming from Germany by way of Denmark, precipitated at first a wordy war of various schools and tendencies, after which came a season of really brilliant production. In the soulful verse of Wallin (1779-1839); in the best work of the arch-Romanticist Atterbom (1790-1855); in the fine spirituality and exquisite workmanship of Stagnelius (1793-1823); in the stirring Northern poems of Geijer (1783-1847), who was destined to become, next to Fryxell, perhaps, his country's greatest historian; in the productions of the brilliantly endowed but erratic and uneven Almqvist (1793-1866); and of several minor poets like Sjöberg (1794-1828) and Nicander (1799-1839); but above all in the splendid talent of Tegnér (1782-1846), who won world-wide fame with his romanticized *Frithiof's Saga*—the national genius found a richer expression than at any time before or since.

In the mid-century period the prominent names are Fredrika Bremer (1801-65), once widely read at home and abroad, and Runeberg (1804-77), a strong rival of Tegnér for the first place of honor in the whole Swedish Parnassus. Somewhat later come Topelius (1818-98), best known for his novels of Finnish history, and Rydberg (1829-95), eminent as poet, novelist, and translator of Goethe's *Faust*. The newer realism is most conspicuously represented by Strindberg (1849—), and recent poetry by Count Snoilsky (1841-1903).

BIBLIOGRAPHY. A good anthology of Old Swedish will be found in Noreen's *Altschwedisches Lesebuch* (Halle, 1892-94), and of the entire literature (to 1830) in the *Läsebok i svensk litteratur* of Hildebrand, Bergstadt, and Bendixson (Stockholm, 1897-98). The old laws have been edited by Schlyter, much of the religious mediæval literature by Klemming. See also the publications of the *Svenska Fornskriftssällskapet*. Of older works on the history of literature the best are Wieselgren, *Sveriges sköna litteratur* (Lund, 1833-49); and Malmström, *Grunddragen af svenska vitterhetens historia* (Örebo, 1866-69). The best work up to date is the *Illustrated svensk litteratur-historia* of Schück and Warburg (Stockholm, 1896 et seq.).

SWEDISH MOVEMENT. See MOVEMENT CURE.

SWEDISH MUSIC. See SCANDINAVIAN MUSIC.

SWEDISH NIGHTINGALE. A popular name given to the Swedish singer Jenny Lind.

SWEENY, THOMAS WILLIAM (1820-92). An American soldier, born at Cork, Ireland. He came to the United States in his boyhood; in 1846 enlisted as second lieutenant in Burnett's New York Volunteers, and fought under General Scott in Mexico. At the outbreak of the Civil War he was in command of the arsenal at Saint Louis, Mo. In reply to efforts of Confederate sympathizers to induce him to surrender that important post he declared that before he would do so he would blow it up. As second in com-

mand he participated in the capture of Camp Jackson in May, 1861; assisted in organizing the Home Guards, and was chosen brigadier-general of that organization, and commanded the Fifty-second Illinois at Fort Donelson. At Shiloh he successfully defended a gap in the Union line. He commanded the second division of the 16th army corps in the Atlanta campaign. In 1866 he took a prominent part in the Fenian invasion of Canada. He retired from the army in 1870 with the rank of brigadier.

SWEET, BENJAMIN JEFFREY (1832-74). An American soldier, born at Kirkland, Oneida County, N. Y. At the age of sixteen he moved with his father to Wisconsin. At the outbreak of the Civil War he helped to raise two regiments, and became colonel of one of them, the Twenty-first Wisconsin. At the battle of Perryville he received a wound that incapacitated him from further service in the field. In the spring of 1864 he was put in command of Camp Douglas at Chicago. In the following July and again in November he defeated plots of the Knights of the Golden Circle (q.v.) to capture Chicago and release the 10,000 Confederate prisoners confined in Camp Douglas. For these services he was promoted brigadier-general of volunteers. From 1869 till 1870 he was United States pension agent at Chicago, and from 1870 till his death was First Deputy Commissioner of Internal Revenue at Washington.

SWEET, HENRY (1845—). An English philologist, born in London. He was educated at King's College and Balliol College, Oxford. He devoted himself to Anglo-Saxon and phonetics. Of his editions of Anglo-Saxon texts the most important are King Alfred's version of Gregory's *Cura Pastoralis* (1871); *Anglo-Saxon Reader* (7th ed. 1894); *Anglo-Saxon Primer* (3d ed. 1883); *Alfred's Translation of Orosius* (1883); *Epinal Glossary* (1883); *Oldest English Texts* (1885). Among his contributions to Anglo-Saxon philology are his *Dialects and Prehistoric Forms of Old English* (1876), and *A Sketch of Anglo-Saxon Poetry*, in Wharton's *History of English Poetry*, vol. iv. (London, 1871). His work in phonetics includes his *Handbook of Phonetics* (1877); *History of English Sounds* (2d ed. 1888); and *Primer of Phonetics* (1890). He is likewise the author of *Words, Logic, and Grammar* (1876); *Elementarbuch des gesprochenen Englisch* (2d ed. 1886); *New English Grammar* (1892); *Current Shorthand, Orthographic and Phonetic* (1892); and a literary study on *Shelley's Nature-Poetry* (1891), of primers of Middle English (1884-86) and of Icelandic (1886), and *The Practical Study of Languages* (1899).

SWEETBRIER. See EGLANTINE.

SWEET CALABASH. See GRANADILLA.

SWEET FERN. A popular name for Myrica asplenifolia and Myrrhis odorata, also known as sweet cicely, both of which have fern-like foliage. The former, being rich in tannin, has been employed as an astringent in domestic medicine; the latter is employed in cooking, for its agreeable flavor.

SWEET FLAG. See ACORUS.

SWEET GALE. See CANDLEBERRY.

SWEET GUM. See LIQUIDAMBAR.

SWEET PEA (*Lathyrus odoratus*). An old-fashioned papilionaceous garden flower which has been brought into prominence and greatly improved in form and color during the closing quarter of the nineteenth century. The plant is a free random grower like other peas, but has perfumed flowers of greater beauty. Sweet peas should be planted as early in spring as the ground can be worked. A rich, deeply prepared clay loam suits them best. Thin, dry soils are not satisfactory. Sweet peas should be sown

SWEET PEA (*Lathyrus odoratus*).

thinly, 2 to 3 inches deep in trenches 4 to 5 inches broad and as deep, 3 to 3½ feet apart. Brush or trellis should be provided when the plants are two inches high, and shallow cultivation should be given all through the growing season and blooming period, gradually filling up the trench. No pods should be allowed to ripen as long as flowers are wanted, as growth ceases with the ripening of the pods. More than 100 named varieties are in cultivation. Two other closely related peas are also cultivated for their flowers—the sweet tangier pea (*Lathyrus tingitanus*) and the perennial or everlasting pea (*Lathyrus latifolius*). Both have long been in cultivation in Europe. The latter, which is very hardy, has many-flowered clusters, large standard, scentless flowers, strongly veined leaflets, and broad, hairless pods. Consult: Hutchins, *All About Sweet Peas* (1894); id., *Sweet Peas Up to Date* (Philadelphia, 1897); New York Cornell Agricultural Experiment Station Bulletins 111, 127.

SWEET POTATO, or BATATAS (*Ipomœa Batatas*). A perennial plant of the natural order Convolvulaceæ, with long creeping stems, heart-shaped leaves on long stalks, and variously lobed, large purple flowers much resembling those of the best known species of Convolvulus, and large oblong or elongated roots. Authorities differ as to whether it owes its origin to East India or America, but it is now cultivated in all tropical and sub-tropical countries for its sweet, wholesome roots, which are highly esteemed as an article of food.

The sweet potato is propagated by sets obtained from the tubers sprouted in a specially

prepared bed and when about four inches tall planted 18 inches asunder in rows 3½ feet apart in the field; the later vine cuttings, which are commonly used in the Gulf States and as far north as Virginia, require from 90 to 105 days to mature their roots. The crop grows best in a warm, sandy, well-drained soil. It requires clean cultivation. Early digging yields only one-half to two-thirds as much as may be obtained from the matured crop, which averages from 250 to 275 bushels per acre. The roots should be harvested before frost and when the ground is dry. The roots must be stored in a rather warm, dry place, as otherwise heavy losses are almost sure to occur from rotting. The so-called 'yams' grown in the United States are all sweet potatoes.

The most serious diseases of the sweet potato destroy the fleshy roots. The black rot (*Ceratocystis fimbriata*), which appears as greenish black, irregular spots which increase in size and eventually destroy the whole root, may be spread through planting diseased tubers in the seed bed or through the presence of the fungus in the soil. At the New Jersey Experiment Station sulphur in the soil has been used with success as a preventive. Dry rot (*Phoma batatæ*) dries, wrinkles, and fills the roots with powder. It attacks the whole root in the field. Rotation of crops and destruction of diseased material are recommended as preventives. A soft rot (*Rhizopus nigricans*) attacks stored roots, usually commencing at places where the skin has been broken. Since moisture favors its spread, sweet potatoes should be stored in well-ventilated, dry rooms. A leaf spot (*Phyllosticta bataticola*) often attacks and turns the foliage white, and a leaf mold (*Cystopus ipomœæ-panduranæ*) turns the leaves, especially the older ones, brown. Spraying with Bordeaux mixture or other fungicide (q.v.) is recommended for these last two and the first disease.

As ordinarily prepared for the table the skin constitutes on an average 20 per cent. and the edible portion 80 per cent. of the root. The edible portion has the following percentage composition: water, 69.0; protein, 1.8; fat, 0.7; nitrogen-free extract, 27.4; and ash, 1.1 per cent., the fuel value being 570 calories per pound. Like ordinary potatoes, sweet potatoes are a succulent food, the chief nutrient being carbohydrates, the principal of which is starch. Sugars are also found, 2.5 per cent. cane sugar and 3.4 per cent. invert sugar being the average amount found in a large number of analyses. In addition to the quantities consumed in the fresh state, sweet potatoes are also canned and evaporated. They are sometimes fed to farm animals, especially pigs. To secure the greatest profit the pigs should harvest the crop and some nitrogenous feed like cowpeas should also be fed. See Plate of YAM, SWEET POTATO, ETC.

SWEET-POTATO INSECTS. The leaves of the sweet potato are punctured by a small bronzed flea-beetle (*Chætocnema confinis*), which eats channels along the veins soon after the plants have been set out and causes the leaves to shrivel. The most serious of the insect enemies of the crop are several species of tortoise-beetles. (See TORTOISE-BEETLE.) The commonest species are the two-striped tortoise-beetle (*Cassida bivittata*), which is about one third of an inch long, the tortoise-shell yellow and has two black stripes on each wing-cover. The larva is dirty yellowish white and covers itself with cast skins and excrement. It gnaws irregular holes in the leaves underneath which it transforms to pupa. The golden tortoise-beetle (*Coptocycla aurichalcea*), which is more abundant, resembles gold tinsel and is beautifully resplendent. The larva is dark brown and feeds like the previous species. Arsenical sprays have been recommended.

SWEET-SCENTED SHRUB. See CALYCANTHUS.

SWEET SOP (*Anona squamosa*). A bush or small tree of the natural order Anonaceæ, a native of tropical America and introduced in other warm countries. The scaly greenish fruit has a soft, somewhat mealy, sweet, and luscious pulp with a musky aromatic odor and flavor. It is much used, generally raw, but sometimes cooked, and has proved valuable during famines in Hindustan.

SWEET SULTAN. A garden plant. See CENTAUREA.

SWEET VERNAL GRASS. A slender European grass (*Anthoxanthum odoratum*), about 18 inches tall and bearing a loose cylindrical spike of flowers. It is noted for its pleasing odor due to coumarin, which is most noticeable when the plant is in flower. It is often mixed with other grasses to give flavor to hay, but is not considered equal in feeding value to timothy, orchard grass, etc. See Plate of GRASSES.

SWEET WILLIAM, WILD. See PHLOX.

SWELL (AS., OHG. *swellan*, Ger. *schwellen*, to swell; possibly connected with Gk. σαλεύειν, *saleuein*, to toss, Lat. *salum*, open sea). A term applied to a local thickening of a mineral deposit. The phenomenon is not uncommon in many metalliferous veins, and is caused by local expansions of the ore-bearing fissure, due to dynamic action or solution. In coal seams a similar phenomenon is often met with, but the swell here is caused by movements of the floor and roof of the coal bed.

SWELL. In music, a set of pipes in an organ, forming a separate department, which are capable of being increased or diminished in intensity of sound by the action of a pedal, or by a series of shades or shutters overlapping each other like Venetian window-blinds, within which the pipes in question are inclosed. The first recorded swell organ was made in 1712 by Jordan, and in 1763 Shudi introduced the so-called Venetia swell, but the compass of all the early swells was very incomplete. See ORGAN.

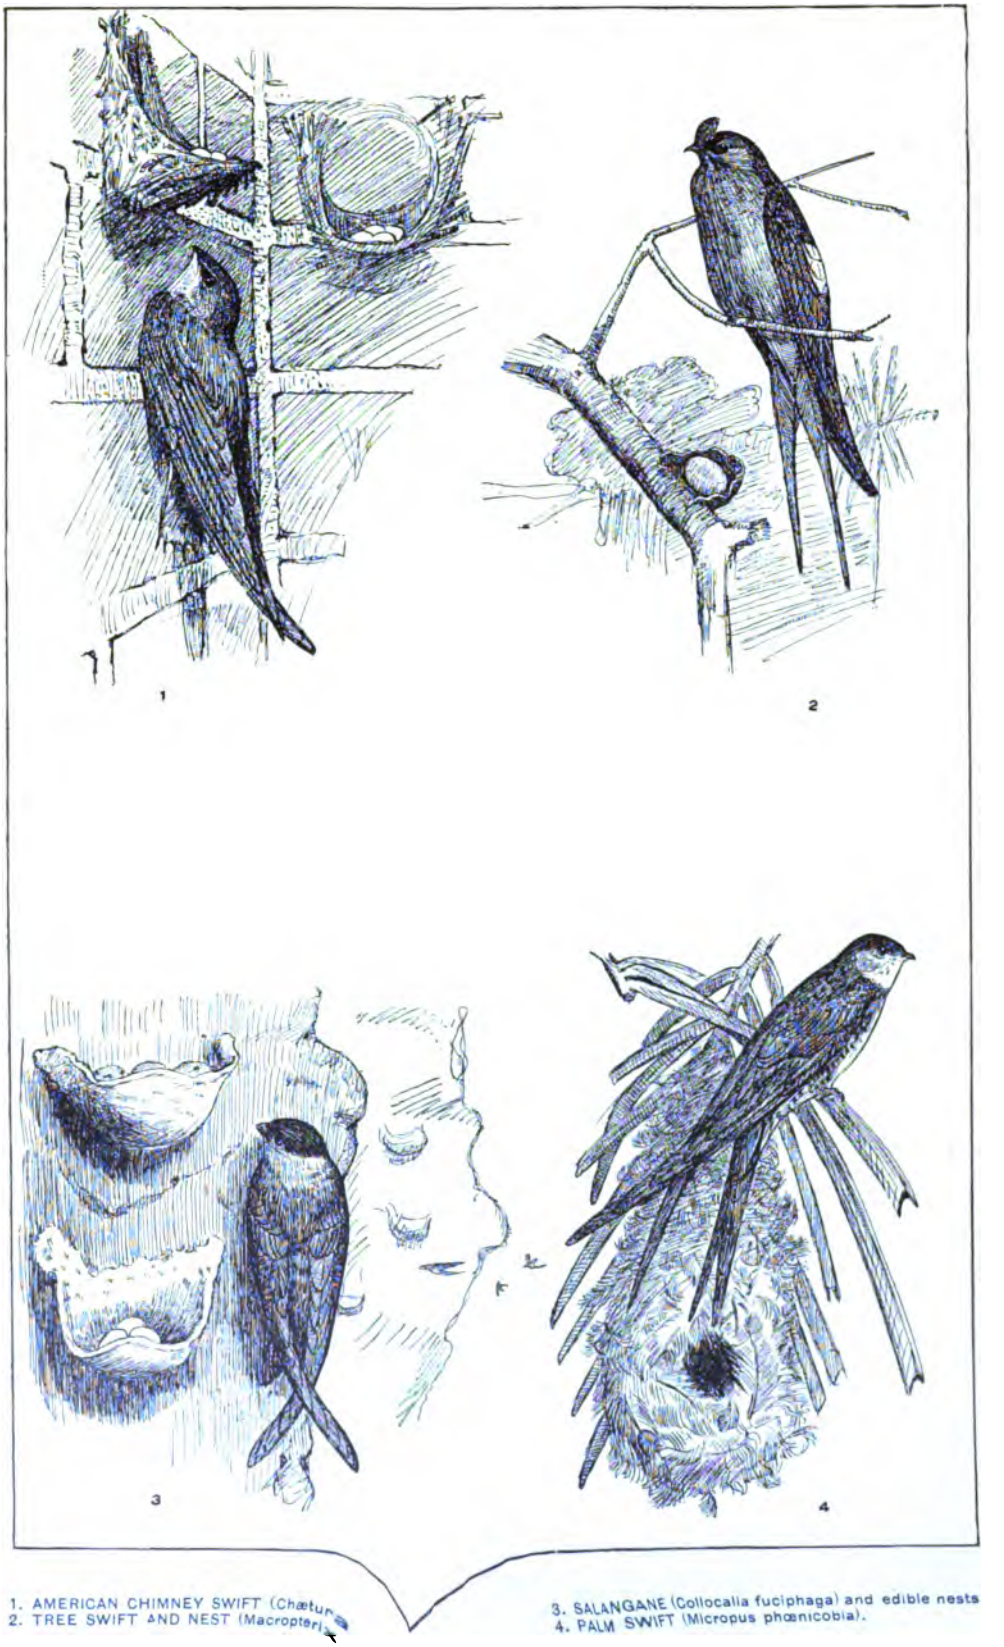
SWELLFISH. One of the many names applied to plectognath fishes, especially of the family Tetraodontidæ, which inflate their bodies with air until they become globe-like and the spines of their skin rigid, making them unpleasant morsels for an enemy to swallow. A familiar example is *Tetraodon turgidus*, of the Eastern American coast-waters, also called 'swell-toad' and 'puffer.' Compare GLOBEFISH. See Plate of PLECTOGNATH FISHES.

SWELL SHARK. A small, voracious gray shark (*Catullus uter*) of the family Scylliidæ, common on the Pacific Coast from central California to Chile, and often taken in lobster-pots. When caught it will inflate its stomach with air,

until its thickness is equal to a third of its length, and will float belly upward until it supposes the danger past; hence its vernacular name. See Plate of LAMPREYS AND DOGFISH.

SWETCHINE, svĕch-ĕn', ANNE SOPHIE SOYMANOFF (1782-1857). A Russian-French author, born in Moscow. Her father was Soymanoff, the founder of the Moscow Academy. She married in 1799 General Swetchine and established at Saint Petersburg a *salon* of much distinction, frequented by émigrés. Thus she came into touch with Joseph de Maistre in 1815, and was by him converted to Roman Catholicism. In the next year she moved to Paris, where her equally famous *salon* took on a distinctly religious tone. Her writings, all of a religious or contemplative character, are edited with a *Life* by Falloux (Paris, 1860); her *Lettres* by the same editor (ib., 1862; 5th ed. 1881), who added a journal of her *Conversation* (ib., 1863), and *Lettres inédites* (ib., 1866). Her letters have been translated by H. W. Preston (Boston, 1867). Consult: Sainte-Beuve, *Nouveaux lundis* (vol. i., Paris, 1863-72), and Scherer, *Etudes critiques sur la littérature contemporaine*, vol. i. (ib., 1863).

SWETE, swēt, HENRY BARCLAY (1835—). An Anglican clergyman, especially distinguished for his work in textual criticism. He was born at Redlands, Bristol, and was educated at King's College, London, and at Caius College, Cambridge. In 1877-90 he was rector of Ashdon, Essex; in 1882-90 professor of pastoral theology at King's College, London, and in 1890 was made regius professor of divinity in Cambridge. Among his published works are two essays on the *History of the Doctrine of the Holy Spirit* (1873, 1876), an edition of *Theodore of Mopsuestia's Commentary on the Epistles of Saint Paul* (1880-82), *The Old Testament in Greek* (1887-94; 2d ed. 1895-99), *The Akhmîn Fragment of the Gospel of Saint Peter* (1893), *The Psalms in Greek According to the Septuagint, with the Canticles* (1889; 2d ed. 1896), *The Apostles' Creed in Relation to Primitive Christianity* (1894; 3d ed. 1899), *Church Services and Service Books Before the Reformation* (1896), and *An Introduction to the Old Testament in Greek* (1900).



SWEYN, swān, **SWEGEN**, svā'gen, or **SWEND**, svĕnd. A King of Denmark, father of Canute (q.v.). See DENMARK.

SWIETEN, svē'ten, GERARD VAN (1700-72). A celebrated Dutch physician and scholar, born at Leyden, where, after studying philosophy at Louvain, he pursued medicine under Boerhaave, whose most distinguished pupil he became. Called to Vienna in 1745 as physician in ordinary to Maria Theresa, he instilled new life into every branch of science, but especially promoted reforms in the study of medicine, which, as director of the faculty, he raised to a high standard through his own teachings as well as by the appointment of famous specialists to chairs at the university. Reforms in the other faculties presently followed, and although greatly hampered by the intrigues of the Jesuits, Van Swieten held his own against them here as well as in the supervision of censorship, in which considerable authority was accorded him as custodian of the Imperial library, and of which he was finally appointed chairman in 1759. In science he sought his fame as an expositor of his teacher Boerhaave. His *Commentaria in Hermanni Boerhaave Aphorismos de Cognoscendis et Curandis Morbis* (new ed. 1787-92) hold a permanent place in medical literature. In 1758 Van Swieten, having saved the life of the Empress, was created a baron.

His son GOTTFRIED (1733-1803) succeeded him as custodian of the Imperial library and was an intimate friend of Haydn and Mozart. For the former he adapted the text of the *Creation* from the English and wrote the text of *The Seasons*.

SWIFT (AS. *swift*, fleet, rapid; connected with *swāpan*, Eng. *swoop*, *sweep*, OHG. *sweifan*, Ger. *schweifen*, to rove). A bird of the family Cypselidæ, nearly related to the humming-birds. The swifts are widely distributed, and some are only found in tropical countries; others are birds of passage, and spend the summer in colder parts of the world. Many are popularly called swallows, as, for example, the chimney-swift of the United States, almost always called 'chimney-swallow.' This confusion is due to a resemblance in the long, pointed wings, the small, widely gaping bill, the weak feet, and to the habit of capturing their insect prey by untiring hunting in the air. About seventy-five species of swift are known, half of which are American, although only four occur in the United States. Swifts are mostly dull-colored birds, black, brown, gray, and white, and are seldom over seven inches in length or more than twice that across the wings. They are remarkable for the development of the salivary glands, the secretion of which is used in building the nest. The latter may be nearly pure saliva, as in the edible nests of the salangane (q.v.), or, as is more commonly the case, may be composed of grass, twigs, or other vegetable matter, glued together and to the support by saliva. The nests are attached to cliffs, the interior of chimneys, or hollow trees, the spathes of palm blossoms, or the leaves of palms, etc. The eggs are pure white, unspotted. The only swift common in the United States is the well-known chimney-swift (q.v.). Along the Pacific Coast occurs also the great black swift (*Cypseloides niger*), whose range includes the West Indies and Mexico and extends north to British Columbia. It breeds on inaccessible cliffs, and is still little known. Another large swift (*Cypselus melanoleucus*), which has the chin, throat, and breast white, occurs in the Southwestern United States, north to Wyoming and Utah, and it also breeds on practically inaccessible cliffs. To the same genus as the last-named species belong the best-known European forms. In this genus, which contains about twenty-five species, three-fourths belonging to the Old World, the tail is usually forked, the legs and toes are feathered, and all the toes are directed forward. The common and widespread European swift is *Cypselus apus*. Another notable species is the alpine swift of the mountainous parts of South Europe. To this same genus belong the palm swifts of the West Indies, of which a Jamaican species (*Micropus phœnicobia*) is noteworthy on account of its nest, which when placed in a palmetto is glued to the surface of one of the great fronds and formed of silk-cotton in the shape of a bag or watch-pocket open at the side. Some of the most curious and interesting swifts dwell in the Orient. One genus

SWIFTS AND THEIR NESTS

1. AMERICAN CHIMNEY SWIFT (Chætura
2. TREE SWIFT AND NEST (Macroptery
3. SALANGANE (Collocalia fuciphaga) and edible nests
4. PALM SWIFT (Micropus phœnicobia).

(Macropteryx) contains the tree-swifts, whose plumage is peculiarly soft, the tails deeply forked and the head crested. They are shy and breed in rocky jungles, forming a little cup-shaped nest of flakes of bark glued together with saliva and attached to the side of the branch of a tree. There is only one egg, which (as is the case with all the family) is pure white. Five species are found in the Indo-Chinese region and eastward to the Solomon Islands.

SWIFT, BENJAMIN. The pseudonym of the English novelist William Romaine Paterson (q.v.).

SWIFT, GUSTAVUS FRANKLIN (1839-1903). An American merchant, born at Cape Cod, Mass. After various business experiences he engaged in meat-packing in Chicago, and was the first to ship meat long distances successfully. He founded and was president of the corporation of Swift and Company, one of the largest packing firms in the United States, and was a prominent member of many other similar concerns. His business enterprise did much for the trade development of Chicago.

SWIFT, JONATHAN (1667-1745). The greatest of English satirists, born in Dublin, November 30, 1667. He was of Yorkshire origin. His father had been attracted to Ireland by the prospect of political preferment, but died before Jonathan's birth. When he was six years old, his uncle Godwin sent him to Kilkenny School, the Eton of Ireland, where Congreve and Berkeley were his contemporaries. At fifteen he was sent to Trinity College, Dublin. At Trinity the lad read much history and poetry, but was so disdainful of the ordinary curriculum and of college regulations that his degree was only granted to him by a special grace. The disturbances of the Revolution of 1688 drove him to England, and in the following year he obtained employment as secretary to Sir William Temple (q.v.) at Moor Park, in Surrey. Swift found the position trying, though he calls Temple "a man of sense and virtue." In 1694 he quarreled with his employer and returned to Ireland to seek ordination, obtaining the small living of Kilroot, near Belfast. But he soon wearied of rural isolation and in 1696 he went back to Moor Park. Perhaps the impelling motive was the presence there of Esther Johnson, subsequently immortalized as "Stella," a poor relation of Temple's. Swift had a hand in her education; she was now, at fifteen, growing into a beautiful woman, with "hair blacker than the raven and every feature of her face in perfection." Swift remained at Moor Park until Temple's death in 1699. His sojourn there, however galling some incidents of it may have been to his pride, was of inestimable value to him. Besides the daily association with a statesman and a man of culture, he had time for an enormous amount of reading and for practice in writing. His only relics, however, of this period are some Pindaric odes, a species of composition for which he was little qualified and which Dryden characterized frankly with the judgment, "Cousin Swift, you will never be a poet."

His first prose composition betrayed his resentment. This was *The Battle of the Books*, a burlesque of the controversy then raging over the relative merits of the ancients and moderns, in which for the first and last time his satire recoiled on himself. He returned once more to Ireland, as secretary and chaplain to Lord Berkeley, but lost the secretaryship and did not get the deanery of Derry, which he had expected. He was, however, appointed to the rectory of Agher, with the vicarages of Laracor and Rathbeggan. For the first time his own master, Swift showed that stern regard for duty which characterized him, and gained the respect, if he failed to influence the convictions, of his Catholic neighbors. He realized himself that he was a poor preacher, calling his sermons 'pamphlets.' He soon began his career as a political pamphleteer, which was to be so epoch-making, with *A Discourse on the Dissensions in Athens and Rome* (1700), really a defense of Somers and the other Whig lords threatened with impeachment. In 1704 he published the *Tale of a Tub*, the most amusing of his satirical works, the most strikingly original, and the one in which the full compass of his powers was most perfectly displayed. With matchless irony he ridiculed many forms of pretentious pedantry, mainly in literature and religion. The book led to many doubts of his orthodoxy and injured his chances of ecclesiastical preferment.

Though nominally a Whig, Swift differed from his party on important questions. He hated its war policy and its alliance with dissent. These differences, along with the failure to gain anything from the connection, made it easy for him to break from his former allies. In 1710 the Tories came into power with Harley and St. John at their head and Swift was easily won over to their side. He turned upon the Whigs with a series of brilliant squibs, assumed the editorship of the *Examiner*, the Tory organ, November 2, 1710-June 14, 1711, and produced several independent pamphlets, in all of which he ably defended the policy of the Tories. Of these particular papers the most powerful was the *Conduct of the Allies* (November, 1711), in which the position was maintained that the Whigs had prolonged the Continental War out of self-interest. Swift certainly led the way to the dismissal of Marlborough and the Peace of Utrecht (1713). For three years Swift was among the most conspicuous men in politics and society. His advent marks a new era in English politics, with the accession of public opinion, fostered by him more than by any other man, to supreme power.

He comes into full light in September, 1710, with the beginning of his *Journal to Stella*. He had invited her in 1701 to Ireland, with her friend Mrs. Dingley. They lived in his house at Laracor and Dublin when he was absent, and in lodgings near by when he was present. The diary letters which he sent to Stella and Mrs. Dingley, ending with April, 1713, compose one of the most interesting documents that ever threw light on the history of a man of genius. In London he lodged close to Mrs. Vanhomrigh, whose daughter Hester (called Vanessa by him) fell in love with Swift, and hugged the chains to which Stella merely submitted. In 1714 the Tory Ministry fell, Queen Anne died, and Swift's power was gone. In spite of the Queen's distrust of him, he had been appointed to the deanery of Saint Patrick's in Dublin, in 1713, and thither he now retired, no doubt hoping that the move would settle his complications for him. But, as luck would have it, Vanessa's mother died and she followed him to

Celbridge, in the near neighborhood. It is possible that in 1716 Swift may have married Stella. He undoubtedly loved her and shows a tenderness for her such as he never displays in any other case. From 1717 to 1720 he and Vanessa remained apart, but in the latter year he began to pay her regular visits. In 1723 Vanessa took the desperate step of writing to Stella. Swift rode down to Marley Abbey, where she was staying, with a terrible countenance, petrified her with a frown, and departed, flinging on the table a packet containing her letter to Stella. Vanessa died within a few weeks, leaving behind her the poem he had written for her, *Cadenus and Vanessa*, and their correspondence.

Five years afterwards Stella followed Vanessa, and the wretched lover sat down the same night to record her virtues in language of unsurpassed simplicity. A lock of her hair is preserved with the inscription in Swift's handwriting, most affecting in its apparent cynicism,"Only a woman's hair." Between the death of Vanessa and that of Stella, as though withheld by an evil fate until he could no longer enjoy it, came the greatest political and literary triumph of Swift's life. He had fled to Dublin a broken man, politically extinct; a few years raised him to the summit of popularity, though power was denied him. In 1724 he took Ireland by storm with the *Drapier Letters*, a series of wonderfully effective pamphlets, directed against the patent granted to one Wood, a hanger-on of the Court, for coining copper halfpence in Ireland.

The noise of this success had hardly died away when Swift acquired more lasting glory by the publication of *Gulliver's Travels*. Few books have added so much to the innocent mirth of mankind as the first two parts of *Gulliver*. With the omission of certain passages, it is one of the most delightful children's books ever written. Yet it has been equally valued, as Swift meant it to be, for an unrivaled satire on mankind. He seems to have solaced himself with its composition in the early years of what he called his exile; and if the later books show his most savage temper, it is well to remember that they were written during the years when he was attacking political corruption and when his private happiness was being destroyed. In 1726 he brought the completed manuscript to England with him and it was published anonymously in the winter of that year, meeting with instantaneous success.

His last years, however, were clouded by constantly increasing torture from disease. He governed his cathedral with great strictness and conscientiousness, and for years after Stella's death held a sort of miniature court at the deanery. But death was becoming more and more real and welcome to him. His regular farewell to a friend in these latter years was, "Good night—I hope I shall never see you again." A period of absolute mental decay closed with his death on October 19, 1745. He was buried in his cathedral in the same coffin with Stella, with the epitaph written by himself, "Here lies the body of Jonathan Swift, D.D., dean of this cathedral, where burning indignation can no longer tear at his heart. Go, traveler, and imitate if you can a man who was an undaunted champion of liberty."

Swift's character, as a whole, forms a fascinating psychological study. From some passages of his life he would appear a heartless egotist; and yet he was capable of the sincerest friendship, and could never dispense with human sympathy. Thus an object of pity, as well as awe, he is the most tragic figure in the literature of the eighteenth century—the only man of his age who could be conceived as affording a groundwork for the creations of Shakespeare. "To think of him," says Thackeray, "is like thinking of the ruins of a great empire." Nothing finer or truer could be said.

Consult his *Works*, edited by Sir Walter Scott (19 vols., Edinburgh, 1814 and 1824); *Prose Works* (the best edition) edited by T. Scott, with introduction by W. E. H. Lecky (Bohn's Library, 8 vols., London, 1897-99); various selections, by S. Lane-Poole (ib., 1884-85), by W. Lewin (Camelot Series, ib., 1886), by H. Morley (Carisbrooke Library, ib., 1889), and by H. Craik (Oxford, 1892-93); *Unpublished Letters* (edited by G. B. Hill, London, 1899). The best recent lives of Swift are by H. Craik (London, 1882), Leslie Stephen (ib., 1882), and Churton Collins (ib., 1893). Consult also Forster's incomplete *Life* (1875); Wilde, *Closing Years of Swift's Life* (Dublin, 1849); Lane-Poole's *Notes for a Bibliography of Swift*, reprinted from *The Bibliographer* (London, 1884).

SWIFT, Joseph Gardner (1783-1865). An American soldier, born at Nantucket, Mass. He graduated at the United States Military Academy in 1802, being the first graduate of that institution; became a captain in 1806 and a major in 1808, and in July, 1812, was promoted to be colonel and chief engineer of the United States Army. In the War of 1812 he served as chief engineer of the army under General Wilkinson, in the Saint Lawrence campaign of 1813; later had charge of the construction of the fortifications of New York harbor; was brevetted a brigadier-general in February, 1814; and was superintendent of the United States Military Academy by virtue of his office as chief of engineers from 1812 to 1817. He resigned from the army in November, 1818; superintended the construction of the New Orleans and Lake Pontchartrain Railroad in 1830-31; was for many years in charge of harbor improvements on the Great Lakes; and was engaged in numerous other engineering enterprises.

SWIFT, Lewis (1820—). An American astronomer, born at Clarkson, N. Y. He was educated at Clarkson Academy and about 1854 took up the study of astronomy. He was noted for his numerous discoveries of comets and nebulæ previously uncatalogued. He became director of the Warner Observatory, Rochester, N. Y., 1882. His 16-inch telescope at that institution was presented to him as a gift by the citizens of Rochester and was subsequently removed by him to his present observatory on Echo Mountain, Pasadena, California.

SWIFT, Lindsay (1856—). An American librarian, bibliographer, and literary historian, born in Boston. A graduate of Harvard (1877), he became associated in various bibliographical capacities with the Boston Public Library, and made valuable contributions, editorial and original, to the study of early American literature and history. The most noteworthy of his books is *Brook Farm* (1900), an essay on New Eng-

land transcendentalism. Noteworthy also is a monograph on *Massachusetts Election Sermons.*

SWIMMING (from *swim*, AS., OHG. *swimman*, Ger. *schwimmen*, to swim; connected with Goth. *swumsl*, pond, and ultimately with Eng. *swamp*). The act by which an animal progresses in the water. Man is the only animal who does not swim naturally, yet keeping the head above the water is an act which most human beings may easily learn.

The swimming of quadrupeds amounts simply to walking in the water, whereas man has adopted many kinds of stroke besides the dog-paddle method by which most land animals propel themselves. These methods involve swimming on the breast, with a broad sweep of the arms and a frog-like motion of the legs; swimming on the side, and swimming on the back. He has also learned to float and to tread water. In the latter case the body is held in a perpendicular position and the hands and feet beat downward. The old side stroke is the favorite style for long-distance racing. It consists of three alternate motions, an under-arm and an over-arm stroke, and a scissors leg stroke, coming between the two arm strokes. The Trudgeon stroke is a form of swimming introduced into England a few years ago from the South Pacific. This is now very popular among all civilized swimmers, and is one of the fastest of all strokes for short distances. It consists of alternate overhead strokes, with a frog kick simultaneous with one of the arm strokes, the body swimming on the belly. A modification of this stroke was introduced a few years ago by Alexander Meffert, the famous American amateur mile-champion, in which the head and forearm are kept submerged as the body is pushed forward, the body being turned from the waist and the face brought above the water as the body checks between strokes. This style of swimming admits of freer animation and obviates any cramped position of the head. It is used by some of the best American swimmers.

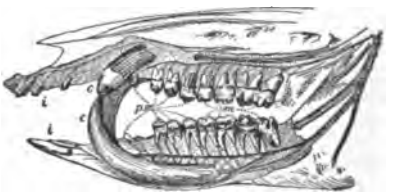
The home of organized swimming is England. International swimming races between the various parts of the United Kingdom are held annually, the universities of Oxford and Cambridge include swimming on the list of inter-university sports, and inter-collegiate competitions take place within the universities themselves. An amalgamation of clubs in 1869 first brought swimming under organized control, and this association developed, under several successive names, into the Amateur Swimming Association in 1886. England and the Australian colonies easily head the world in feat swimmers. In addition to the Amateur Swimming Association, great practical good has come to the art by the establishment of classes of already good swimmers to be further instructed in the methods of rescuing drowning persons, and resuscitating those apparently exhausted. Diving has been carried to a greater degree of perfection in Sweden than in any other country. Usually the English practice has been confined to the standing or running dive with the succeeding underwater swim, a very useful accomplishment where life-saving is the object, as the body thereby enters the water with a strong impulse in the line of the desired direction: but in Sweden the dive from platforms from forty to sixty feet above the surface, singly and in groups, and either directly or horizontally, or with intermediate somersaults, has been developed.

In the United States, the West is ahead of the East both in general interest and participation, especially beyond the Rockies, where several world's records have been approached. The first championship races were held in 1877 by the New York Athletic Club, and were annual thereafter up to 1888, excepting the years 1879-82. In 1888 the management was ceded to the Amateur Athletic Union. In 1896 an indoor meet was added. The development in time made is shown in the record of the first meet in 1877, when R. Weissenborn won the mile in 45.44¼, a quarter of a minute slower than the present American record. The 100-yard event was established at the third meet, 1883, when A. F. Camacho won in 1.28¼.

Water polo is a department of swimming that has become very popular since it was first recognized as a sport, and there are leagues and national and international championships in Ireland, England, and Scotland (where the game is called water football), Wales, the United States, Canada, India, Australia, and New Zealand. It is played with an Association football (the round ball) in a bath or open water by seven swimmers on each side. The goals are from 19 to 30 yards apart with goal posts at each end. The game is started by the referee throwing the ball into the centre between the line of teams. The ball can be hit or thrown by any player providing he is not standing and only uses one hand. Fouls are awarded for various breaches of rules, the penalty being a free throw for the opposing party. The duration of the game is 14 minutes, 7 each way; a goal is scored when the ball passes through the goal posts and under the cross bar.

SWIN'BURNE, ALGERNON CHARLES (1837—). An English poet, son of Admiral Charles Henry Swinburne and Lady Henrietta Jane, daughter of the third Earl of Ashburnham. He was born in London, April 5, 1837, and was educated at Eton and at Balliol College, Oxford. There he contributed prose and verse to *Undergraduate Papers*, ed. by John Nichol. After three years he left Oxford (1860) without a degree and traveled on the Continent, visiting Landor at Florence (1864). Returning to England, he became closely associated with his brother romantics, Dante Gabriel Rossetti and William Morris. Having written *The Queen Mother* and *Rosamond* (1860), two dramas recalling the fire of the Elizabethan age, he published *Atalanta in Calydon* (1865), a beautiful lyric drama cast in the mold of ancient tragedy. The next year he awakened violent criticism with *Poems and Ballads*. To his assailants Swinburne replied with unmeasured scorn in *Notes on Poems and Reviews* (1866). Besides the few pieces that reasonably disturbed the moralists, the volume contained melodious lyrics covering a wide range of motives, Hebrew, Greek, and mediæval. Swinburne now composed a series of eloquent odes, which won universal attention and again exposed him to censure. Beginning with "A Song of Italy" (1867), they reach a point where "the heights flash" in *Songs Before Sunrise* (1871), celebrating the conflict between darkness and dawn, tyranny and freedom in revolutionary Europe. In the meantime had appeared several lyrics on other themes, of which the finest was

"Ave atque Vale" (1868), in memory of Baudelaire. In 1865 Swinburne published *Chastelard*, a romantic tragedy on the first period in the career of Mary Queen of Scots. He continued her history in *Bothwell* (1874) and afterwards completed it in *Mary Stuart* (1881). The imposing trilogy is a chronicle history cast in dramatic form with no view to the stage. The poems thus far enumerated fairly represent Swinburne, his originality, his extraordinary command over hitherto unsuspected sources of melody, his passion and vehemence.



With occasional fall in power, Swinburne produced *Erechtheus* (1876), a second and more restrained classical drama; a second series of *Poems and Ballads* (1878); the grand odes to Victor Hugo; various beautiful sonnets; translations from Villon; *Songs of Two Nations* (1875); *Songs of the Springtides* (1880); *Studies in Song* (1880); *Tristram of Lyonesse and Other Poems* (1882), passionate verse haunted by the rhythm of the sea; *A Century of Roundels* (1883); *A Midsummer Holiday and Other Poems* (1884); *Marino Faliero*, a tragedy (1885); *Locrine*, a tragedy (1887); a third series of *Poems and Ballads* (1889); *The Sisters*, a tragedy (1892); *Astrophel and Other Poems* (1894); *The Tale of Balen* (1896); and *Rosamund, Queen of the Lombards*, a tragedy (1899).

The earlier attitude of defiant revolt against the conventional social order, against kings and priests, prevented his appointment as laureate on the death of Tennyson in 1892, though he was acknowledged as the greatest surviving English poet. In his later years, however, the note of rebellion was less violently sounded, and other feelings, characteristically English, the love of the sea and of little children, held a large place in his poems. As an artist in verse, by his unsurpassed command of all the resources of metrical technique, he takes a unique position. He invented a number of new rhythmic forms, and used none of the old without developing new beauties in them. His chief defect was the natural outcome of his exceptional facility of utterance and impatience of restraint, which allows him frequently to pour forth long sequences of sonorous strains with but little regard to sense. In criticism Swinburne's attention is paid chiefly to the Elizabethan dramatists, though he has indeed made excursions elsewhere, not sparing contemporary singers. These essays have been partially collected in *Essays and Studies* (1875), *A Study of Shakespeare* (1880), and *Miscellanies* (1886). Into his prose Swinburne carried something of the passion of his verse. Notwithstanding the occasional exaggeration into which this leads him, and much faulty reasoning, his conclusions are likely to be true. With wonderful insight he sees the truth, but deceives himself when he comes to state the way in which he arrived at it. His prose, too, has caught the alliteration, resonance, and undulating rhythm of his verse. Consult: Stedman, *Victorian Poets* (rev. ed., Boston, 1887); Theodore Wratislaw, *Algernon Charles Swinburne: a Study* (London, 1901); and Shepherd, *The Bibliography of Swinburne* (ib., 1887). Also *The Fleshly School of Poetry* (1871)—a pamphlet in which Robert Buchanan attacked Rossetti and Swinburne—and Swinburne's reply in *Under the Microscope* (1872).

SWINDLING. See FRAUD.

SWIN'DON. A municipal borough in Wiltshire, England, 77 miles west of London (Map: England, E 5). The old market town, the *Svindune* of Domesday, is built on an eminence commanding fine views of the surrounding country; its urban boundaries were enlarged between 1890 and 1900 to include New Swindon on the marshy plain below. The old town, which received a charter for a fair from Charles I., still maintains the characteristics of an agricultural centre with corn and cattle markets. Population, in 1891, 90,350; in 1901, 94,500.

SWINE (AS. *swīn*, Goth. *swein*, OHG. *swīn*, Ger. *Schwein*, swine; connected with Lat. *suinus*, relating to swine, from *sus*, Gk. *ὗς*, *hys*, Av. *hu*, pig, OHG. *sū*, Ger. *Sau*, AS. *sugu*, *sū*, Eng. *sow*, and ultimately connected with Skt. *sū*, to generate, produce, or with Skt. *sūkara*, swine, lit. *sū*, maker). The family Suidæ, containing those cloven-hoofed ungulate mammals whose domesticated races are called hogs or pigs. The swine are closely allied to the Hippopotomidæ, on the one hand, and to the Dicotylidæ on the other; the latter (peccaries, q.v.), indeed, are sometimes included in the term in popular usage. The three families form a group, Suina. Swine differ from hippopotamuses in their smaller size, in the terminal nostrils, and mobile, gristly snouts with which they obtain their food (largely roots and herbs) by grubbing in the ground. Each foot has four digits, two of which are functional, while the others, although elevated, are often useful in preventing the foot from too readily sinking into marshy ground. They are generally hairy, the babirussa (q.v.) being an exception. The dentition is complete and of the character exhibited by the accompanying illustration of a hog's teeth. The great canines form

DENTITION OF SWINE.

i, incisors; *c*, canines (tusks); *pm*, premolars; *m*, molars; the nervous system of the teeth is also shown.

tusks, which in the males (boars) become formidable weapons; and in some cases (as the babirussa) are doubly developed. The food consists largely of vegetable matter, but may include tough roots, nuts, etc., and also flesh, fish, shellfish, etc.; the stomach is simple, and there is no cæcum (except in the peccaries). These animals are somewhat gregarious, often gathering into small bands, and some peccaries form large herds. The boars fight terrifically in competition for the favor of the females (sows), and valorously defend their young (which are usually striped); they are also courageous in resisting all foes, so that the hunting of certain species affords exciting sport. The pork is usually nutritious and palatable. The family is not large, and is mainly tropical in its distribution. The Suidæ are confined to the Old World; the Dicotylidæ to the warm latitudes of Ameri-

ca. The type-genus is Sus, of which the wild boar (see BOAR) of Europe and Asia is the most prominent species. India and the Malayan region have together three other species, and Western Africa possibly a fifth. The African warthogs (q.v.) include two species of the genus Phacochœrus, distinguished from Sus principally by the huge tusks and great protuberances on the face. The Celebesian babirussa (q.v.) represents alone another genus; and the African river-hogs close the list with two species. One genus and two species enumerate the peccaries. See HOG for an account of domestic races.

Fossil forms of the genus Sus are known in rocks of Middle Miocene to Pleistocene time in Europe, India, and Africa. The earliest representatives of the hog family appear in the Eocene of both North America and Europe, and the group reached an important stage of evolution in late Tertiary time. One notable genus, not, however, in the direct line of pig ancestry, is Elotherium of the Miocene, which was about the size of a rhinoceros, with large heavy head, massive shoulders, and small hindbody and narrow chest, and the body supported on stilted legs that terminated in two-toed feet.

SWINEMÜNDE, svē'ne-mụn'de. A strongly fortified port and fashionable resort on the Baltic Sea, in the Province of Pomerania, Prussia, on the island of Usedom, 37 miles north-northwest of Stettin (Map: Germany, F 2). The Swine here connects the Stettiner Haff with the sea. The harbor is fine. Nearly 5000 vessels of 1,700,000 tons cleared the port in 1899. The town has valuable fisheries. Population, in 1900, 10,251.

SWINE PLAGUE. A reputed contagious disease of hogs attributed to the action of a specific organism. For remedial, preventive, and sanitary measures, see HOG CHOLERA.

SWING, DAVID (1830-94). An American preacher, born in Cincinnati. He graduated at Miami University, Oxford, Ohio, in 1852, and began to study theology, but for twelve years, beginning in 1853, he filled the position of professor of languages in his college. In 1866 he was called to the Fourth Presbyterian Church in Chicago and soon became one of the prominent clergymen of that city. In 1874 he was tried for heresy and acquitted, but, as a consequence, he resigned his pastorate and withdrew from the Presbyterian ministry. Many of his congregation sympathized with him and a new church was organized, meeting at first in a theatre and later in the Central Music Hall, where Dr. Swing continued to preach to one of the largest congregations in Chicago till his death. His preaching, though diverging from the verbal standards of 'orthodoxy,' was essentially evangelical and spiritual, as well as marked by intellectual power.

SWIN'TON. A manufacturing town in Yorkshire, England, 4 miles north-northeast of Rotherham (Map: England, E 3). It has railway, iron, glass, and pottery works. Population, in 1891, 9705; in 1901, 12,217.

SWINTON, WILLIAM (1833-92). A Scotch-American author, born near Edinburgh. He came to America in 1843 and studied at Knox College, Toronto, and at Amherst College, with a view to the Presbyterian ministry. Giving up this intention, he became professor in a woman's seminary at Greensboro, N. C., and subsequently in Mount Washington College, New York. On the outbreak of the Civil War he was sent to the front as war correspondent for the New York *Times*, and served principally with the Army of the Potomac, of whose career he was afterwards a historian. In 1869 he was appointed professor of belles-lettres in the University of California. Among his publications are: *Rambles Among Words* (1859); *Campaigns of the Army of the Potomac* (1864, rev. 1886); *The Twelve Decisive Battles of the War* (1867); and several textbooks, including a *Condensed History of the United States* (1871) and *Outlines of the World's History* (1874).

SWINTON AND PENDLEBURY, pĕn'd'l-bĕr-ĭ. A town in Lancashire, England, five miles northwest of Manchester. Cotton manufacture and brickmaking are its chief industries. Population, in 1891, 21,637; in 1901, 27,001.

SWISS FAMILY ROBINSON. A story by the Swiss writer J. R. Wyss, begun by his father and published by him under the title *Der Schweizerische Robinson.* It is the account of a family wrecked on an uninhabited island, whose wants are provided for by the most remarkable resources of the island. The tale is based on the idea of *Robinson Crusoe,* and has been widely popular in many languages.

SWISS GUARD. A famous regiment of royal body-guards in France, composed exclusively of Swiss. This regiment was first constituted by royal decree in 1616. Their fidelity was absolute and on the outbreak of the Revolution of 1789 they were the object of special animosity on the part of the Parisian mob. On August 10, 1792, the Swiss Guards were called on to defend the palace of the Tuileries against the revolutionary mob. After a gallant resistance in the face of overwhelming numbers, the Swiss were ordered to lay down their arms, whereupon most of them were massacred by the infuriated assailants and those who escaped did so with the greatest difficulty. It is estimated that nearly 800 Swiss Guards were slain on that day. It is in memory of their heroic conduct and brave death that the famous Lion of Lucerne (q.v.), designed by Thorwaldsen, was carved in the face of a cliff at Lucerne, Switzerland. A feeble effort to reconstitute the Swiss Guards was made in 1815, and a body bearing that name was organized. But it was a poor imitation of the old corps and was easily dispersed by the revolutionists in 1830. Consult: Pollio et Marcel, *Le bataillon du 10 août* (Paris, 1881); Ternaux, *Histoire de la Terreur* (8 vols., Paris, 1863-81); Morse Stephens, *The French Revolution* (2 vols., London, 1886-91).

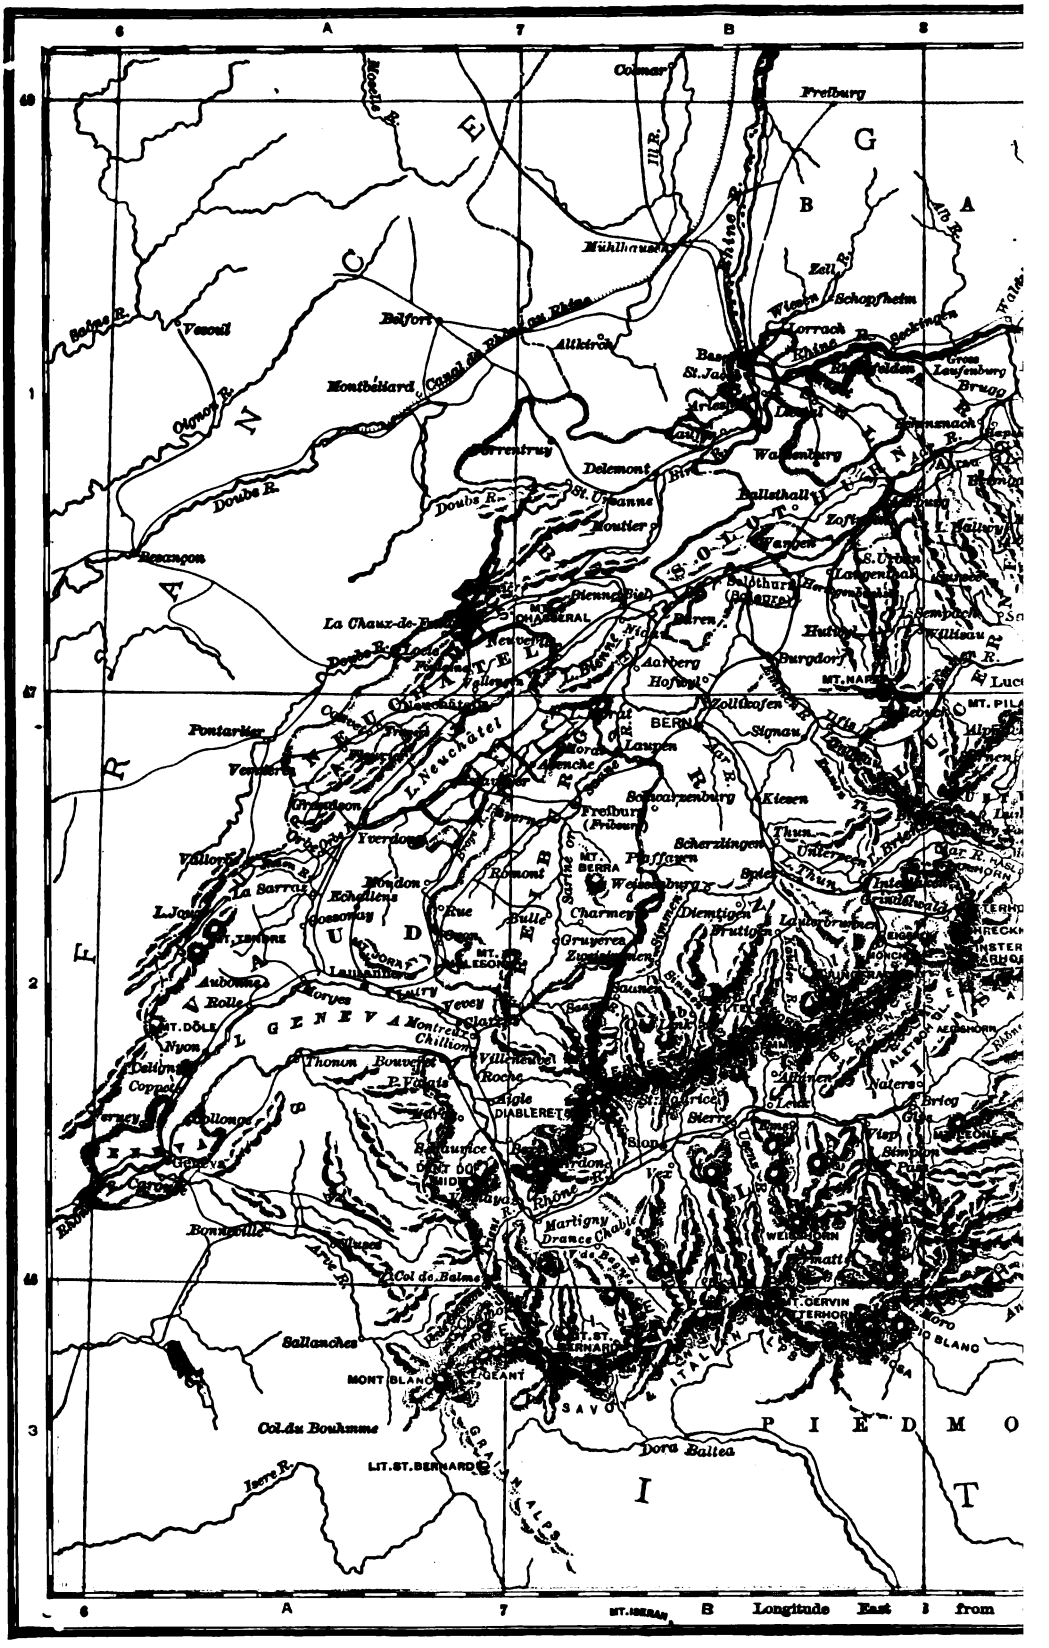
SWITCHMEN'S UNION OF NORTH AMERICA. See RAILWAY BROTHERHOODS.

SWITHIN, swĭTH'ĭn (or, more correctly, SWITHUN), SAINT (?-862). An English ecclesiastic of the ninth century, who was chaplain to King Egbert, and tutor to his son Ethelwulf. In 852 he was consecrated Bishop of Winchester and made one of Ethelwulf's chief councilors. The origin of the tribute called 'Peter's Pence' (q.v.) has been often assigned to him, and he is said to have procured an act of the Witenagemot enforcing for the fist time the universal

obligation of paying tithes. Swithin was buried, according to his own desire, in a place outside of his church at Winchester, where passersby might tread upon his grave and the rain drop on it from the eaves. A century later he was canonized and his body exhumed and buried inside the church. According to the legend this translation, which was to have taken place on July 15, was delayed in consequence of violent rains, which continued without intermission for forty days. Out of this circumstance arose the still current belief that if rain falls on July 15 it will continue to rain for forty days.

SWITZERLAND (Fr. *Suisse*, Ger. *Schweiz*). A country of Europe extending between latitudes 45° 50′ and 47° 45′ N. and longitudes 6° and 10° 25′ E. It is bounded on the west by France, on the north by Germany and the Lake of Constance, on the east by Austria-Hungary (Tyrol and Vorarlberg) and Liechtenstein, and on the south by Italy and the French Department of Haute-Savoie, from which it is separated by the Lake of Geneva. Area, 15,975 square miles. It stretches over 200 miles east and west and 120 miles north and south. The boundaries are complicated and do not follow natural features, excepting that the Jura Mountains form the natural border between Switzerland and France, and the main crest of the Alps is mainly the border on the south side.



Topography. Switzerland is the most mountainous country of Europe, three-fourths of its area being covered with mountains. The central and southern parts are occupied by the Swiss Alps, which spread over nearly three-fifths of the entire area. The Jura Mountains cover the northwestern portion of the country. Between the Jura Mountains and the Alps is the Swiss high plain, where most of the inhabitants live surrounded by these great natural ramparts. The Jura Mountains form a generally southwest-northeast curve. Their summits do not ordinarily exceed 5000 feet, the loftiest in Switzerland being the Dôle, 5505 feet. The folded Juras have fifteen main folds, nearly parallel with one another, none of them extending the whole length of the district. Between the ranges are long valleys, transverse gorges connecting one valley with another; and these features produce scenery of great beauty and variety. Many fine forests of firs cover the upper slopes and an abundance of rich pastures is spread below them, mingling with the fields and vineyards which extend down to the margin of the small lakes that occupy some of the valley bottoms.

The central plain is steeply walled in between the Juras and the Alps. It is about 1300 feet in general elevation. It is a plain chiefly in contrast with the mountains around it and in other countries would be called an elevated region, thickly studded with picturesque hills. It extends in a southwest and northeast direction from the Lake of Geneva across Lake Constance to Württemberg, and has an average width of about thirty miles. Its hills are due chiefly to unequal erosion, the coarse gravel brought down from the Alps (known as 'Nagelflue,' often cemented into a hard conglomerate) having been able especially to resist the destructive action of time and weather. The débris from the Alps, with which it is covered to a great depth, forms its soil, but the disintegrated granites and gneisses contribute too large a proportion of sand and pebbles to make the soil very rich in plant food, though the conditions are more favorable where there is a considerable admixture from the limestone mountains.

The Alps rising from this central plateau are three times as high as the Juras. The utmost complexity appears to mark the arrangement of the towering ranges, masses, spurs, and precipices of the Swiss Alps. The group of Saint Gotthard, however, is the central knot of this mountain world. It is the middle point from which radiate on almost every side the mighty Alpine ranges that fill the centre and the south of Switzerland. The ranges of Ticino from the south, the mountain masses extending from the Simplon in the southwest, the Bernese Oberland from the west, the Titlis group from the north, the Tödi chains (the Alps of Glarus and Schwyz) from the northeast, and the mighty complex of the Grisons from the southeast, all converge upon Saint Gotthard. This group is also a great hydrographic centre. The headwaters of the Rhine flow from its eastern and of the Rhone from its western sides, cutting the Swiss Alps into a northern and a southern half. The Reuss rises from its northern and the Ticino from its southern slopes.

The Swiss Alps are the middle part of the great highland region of South Europe, which extends in the form of a bow from the Gulf of Genoa to the plain of Hungary. The southern Swiss Alps (south of the Rhine and Rhone) begin in the west in the splendid glacier-covered chain of the Pennine Alps, which have their culmination in Monte Rosa (15,217 feet), inferior in height only to Mont Blanc in France. The Mischabelhörner, the Weisshorn, the Breithorn, and the incomparable pinnacle of the Matterhorn are among the Pennines which extend eastward to the Simplon. Over thirty summits exceed 12,000 feet. East of the Simplon extend the Lepontine Alps, the water parting between the Rhine, the Rhone, and the Po, with many valleys deeply excavated by torrents and crossed by a number of important passes to Italy. East of the Ticino Valley and between the Rhine and the Inn are the Alps of the Grisons, whose snows chiefly feed tributaries of the Rhine, many summits exceeding 10,000 feet. Lastly, south of the Inn and the most eastern group of the southern Swiss Alps are the magnificent peaks of Bernina, whose culminating point is 13,288 feet above the sea. These southern Alps are formed of crystalline rocks, while the northern Swiss Alps are chiefly of limestone stupendously folded.

The chains of the northern Swiss Alps are separated one from another by three deep valleys: (1) that of the Aar with the lakes of Brienz and Thun, which carries nearly all the drainage of North Switzerland to the Rhine; (2) the valley of the Reuss with Lake Lucerne; and (3) the Walensee and Lake Zurich. Thus separated the four great groups of the northern Alps are: First, the Bernese Alps (Oberland), the water parting between the Aar and the Upper Rhone, which include the greatest snow mountains of the Alps; first among them the crystalline summits of the Finsteraarhorn (14,026 feet), the Jungfrau (13,672), Mönch (13,440), Eiger, Wetterhorn, Schreckhorn, and others, a compact mass of snowy and rugged peaks with the Aletsch glacier, 16 miles long, the largest of

Switzerland's 600 glaciers. More than 20 of these summits rise over 12,000 feet above sea level. Second, the Titlis Alps, to the east of the Bernese Oberland. Third, the Alps of Glarus and Schwyz, also known by the name of their highest summit in the centre, Tödi (11,887 feet). The Rigi (5906 feet), commanding one of the magnificent views of the Alps, stands in the northwest corner of this group on the shores of Lake Lucerne. Fourth, the lower Alps, between lakes Constance and Zurich, which nowhere reach the snow line. On the whole the southern slopes of the Swiss Alps are steep, but the northern slopes are more gradual. Glaciers and perpetual snow are spread over 800 square miles, or about one-twentieth of the area of Switzerland. See ALPS.

HYDROGRAPHY. Owing to the Alps, the country is especially well supplied with water. Nearly every valley is traversed by a larger or smaller stream, often interrupted by picturesque waterfalls. The country possesses the headwaters of some of the important rivers of Europe—the Rhine, the Rhone, and the Po. The Rhine and its tributaries flowing to the North Sea form the principal system of rivers, but all the rivers in Switzerland are so rapid that they are almost useless for navigation, though their impetuous character fits them for industrial purposes. The only navigable stream of importance is the Aar tributary of the Rhine, which carries a larger volume of water to that river than the Rhine itself supplies above their point of junction. The Rhone, flowing to the southwest and to the Mediterranean, reaches Lake Geneva as a muddy stream and leaves it to enter France as a clear blue river. The Ticino is the largest river sent down by Switzerland to the Po. It has a larger catchment basin than any other Swiss river and is the least fed by glaciers. The Inn flows east through the deep, narrow valley called the Engadine, and falls into the Danube at Passau, where it is much larger than the Danube itself. The glaciers are a source of perennial water supply, and since they melt most rapidly in summer, the Swiss rivers are larger in summer than in winter.

The Alps are the Lake Country of Southwestern Europe. The lakes are remarkable for size, depth, and the grandeur and beauty of the scenery which surrounds them. Among the fifteen important lakes in Switzerland, eleven are in the basin of the Aar and none in the basin of the Inn. Lakes Geneva and Constance, the largest lakes, balance each other at the opposite ends of the country. Lake Geneva, partly in France, is over 200 square miles in area and has a maximum depth of 1000 feet, its bottom extending almost to the level of the Mediterranean. Lake Constance is a little smaller than Geneva, not quite so deep, lies partly in German territory, and is the filter of the Rhine. Lake Neuchâtel, the largest lake entirely in Swiss territory, lies on the tableland, and hence is not so deep as the lakes in the longitudinal mountain valleys. Lucerne, Zurich, Brienz, Thun, and Bienne are also important lakes. Lake Lugano lies partly in Italy, and only nine miles of Lake Maggiore belongs to Switzerland. The Ticino flows through the latter on its way to the Po.

CLIMATE. The distribution of climate is vertical rather than horizontal. On the central plain and in the lower mountain valleys a temperate climate prevails, the mean annual temperature being about 50° F. The mean temperature diminishes on an average by 3° for every thousand feet of elevation, so that the climate in the higher valleys is very severe. Ticino, Vaud, and Geneva enjoy an almost Italian climate, with a mean temperature of 51° to 53.5° F., in which southern fruits ripen. The snow line on the southern side of the Alps is about 10,170 feet above sea level; on the north side the limit of perpetual snow is about 8530 feet. The growth of grain ceases at about 4000 feet. On the higher Alps, which are wrapped in clouds much of the time, the annual precipitation is from 78 to 97 inches; on the central plain it is 33 inches. The Föhn, a warm south wind, causes some destruction by rapidly melting the snow and so producing avalanches and inundations. The climate of Switzerland, on the whole, is not favorable to agriculture, but is stimulating and healthful.

FLORA AND FAUNA. The vertical zones of vegetation in the Alps correspond to the horizontal zones of Europe between latitude 46° and the Arctic Circle. Olives in a few of the low valleys are succeeded by vines and the plants of middle Europe; then come in succession deciduous trees and grains, conifers, the high pastures, and shrubs and mosses, above which rises the region of perpetual snow. Oaks and chestnut trees are abundant only in the more southern valleys, beech trees are numerous up to 4000 feet above the sea, and pines, larches, and fir trees thrive between 4000 and 6500 feet. Agriculture is mainly confined to the regions not above 2500 feet, but the high pastures extend far above the region of tillage.

The wolf, ibex, and chamois are found in the mountains, but all wild animals are becoming very scarce.

GEOLOGY AND MINERAL RESOURCES. The backbone of Switzerland consists of gneiss and granite with outlying strata of the Carboniferous, Triassic, Jurassic, Cretaceous, and Tertiary formations. These strata are all thrown into a succession of gigantic folds, giving rise to great geologic complexity. Four distinct geologic zones, extending across Switzerland from southwest to northeast, are recognized. The limestone Jura region of roughly parallel folds is the first zone. The second is the plain whose rocks are chiefly sandstone covered, to a great extent, by the deposits of the ice invasions. The other zones cover the Alps, the more northern being that of the limestone Alps whose strata are greatly distorted and piled up over one another. The fourth zone consists of the great crystalline masses of the southern Swiss Alps formed of gneiss, granite, and other crystalline rocks and schists. Denudation has reduced the height of the mountains and deepened and lengthened the valleys, the larger rivers having pushed their sources back to the very heart of the mountain groups. The mining industry is of little importance. Building stone, particularly sand and limestone and rock salt, found in three cantons, are the chief mineral products. A little iron ore is mined in the Jura ranges, but the iron industries depend upon imports of material. A small amount of anthracite is mined near Bern of Fribourg, but Germany sends nearly a million tons of coal to Switzerland every year, and France, Austria, and England also contribute important quantities. Asphalt in the Val des

Travers, marble in Uri, Schwyz, and Ticino, slate in Glarus, and rock-crystals of great beauty, are other mineral products.

AGRICULTURE AND STOCK-RAISING. The soil is distributed among nearly 300,000 peasant proprietors representing nearly two-thirds of the population. More than 28 per cent. of the area is unproductive, chiefly the regions above the zone of tillage. Hay and pasturage lands, more important than the cultivated lands, cover 36 per cent. of the surface; the area under forests is 18.4 per cent., while only 16.5 per cent. of the surface is arable. Switzerland derives less support from its agricultural resources than any country of the Continent, excepting Norway. Only Solothurn, Lucerne, Schaffhausen, and Fribourg, among the cantons, produce nearly enough plant food for their own consumption. Wheat is grown up to 2500 feet above sea level, but the crop averages only about 3,500,000 bushels, while over 11,000,000 bushels are imported from other countries, chiefly Russia and Hungary. Rye, oats, and potatoes are the chief crops, but potatoes are imported in large quantities. During the tourist season of 1901 the amount of vegetables brought into the country was about 20,000 tons, of which nearly two-thirds came from Germany, France and Italy contributing most of the remainder. The cultivation of fruit is in a flourishing condition and nearly all the cantons manufacture wine or spirits from it, such as the cherry brandy produced at Basel. In 1901, 78,931 acres were in grapes, the cultivation of the vine commanding careful attention in most of the cantons. The best wine is made in Geneva, Neuchâtel, and Valais. The wine produced (35,800,000 gallons in 1901) does not cover the domestic demand. Orchards are planted everywhere in sheltered places and grapes thrive especially in the warmer soils around Lake Geneva and some other lakes and on the southern slopes of the mountains. The warmer cantons of the south also produce chestnuts, almonds, walnuts in abundance, olives, and even lemons. Switzerland is no longer so rich in timber as formerly, for unscientific forestry has thinned the woods to a large extent. The entire forest area is about 3300 square miles, of which a large portion is now under Government supervision. Every effort is being made to restore this source of wealth to its former magnitude, and in 1901 there were planted 23,731,376 trees.

As the climate and soil are especially favorable for hay and pasturage, the animal industries are more important than tillage. In comparison with cattle (1,340,375 in 1901) the other domestic animals are much inferior in number and importance. Cattle-breeding is carried on in all the cantons, and in the higher regions it is the chief and sometimes the only resource of the inhabitants. Switzerland is famous for its cheese, and the chief agricultural industries are the manufacture of cheese and condensed milk. The annual production of cheese amounts to about 500,000 cwts., of which three-fifths is exported to all quarters of the globe. The best cheeses are made in the Emmenthal, Maderanthal, Ufernthal, and in Gruyères. Many Swiss cattle are exported for breeding purposes, while, on the other hand, the great influx of tourists in summer makes it necessary to import an average of about 50,000 beef cattle a year, chiefly from Austria and Italy, to make up for the local deficiency in beef. Next in number are goats (354,634), which abound in the higher Alpine cantons and are reared for their skins, flesh, and milk. In 1901 the horses numbered 124,896; mules and asses, 4866; sheep, 219,438; and hogs, 555,261. The lakes abound in fish, and pisciculture is promoted by 155 establishments that produce enormous quantities of fry.

MANUFACTURES. Switzerland is a great manufacturing country, though it lacks coal, iron, and seaports. Its advantages are abundant water power, markets in the adjoining countries in which to buy raw materials and sell manufactured products, good connections with seaports, and the diligence, perseverance, and skill of the people. Nearly as many persons are engaged in manufactures as in agriculture. Large quantities of the manufacturing output are produced in the homes. The textile and metal industries are of greatest importance. The cotton industry, which competes even with English manufactures, is centred chiefly in the cantons of Zurich, Glarus, Saint Gall, and Appenzell. Swiss cotton cloths noted for fineness of texture and excellence of dyes and prints are sent all over the world. The well-known machine-made lace and embroidery industry of Switzerland employs about 10,000 machines and 17,000 workers in Saint Gall, Appenzell, and Neuchâtel. The great centres of the silk industry are Basel, where all kinds of silk ribbons are produced, and Zurich, where dress goods are woven. Watchmaking and machinery lead in the metal industries. The most important centres of watchmaking are Geneva, Chaux-de-Fonds, and Locle. The industry was once very prosperous, but it has suffered severely of late years from the competition of the machine-made watches of the United States. The Swiss, however, have regained a large part of their export trade by the introduction of machinery and the manufacture of the cheaper grades of watches, which they produce by the hundreds of thousands every year, five-sixths of them being sold in foreign countries. The manufacture of jewelry and musical boxes, wood-carving, straw-plaiting, leather-making, and tanning are also very important industries. The well-known machine works of Zurich, Winterthur, and Geneva export a considerable part of their output.

COMMERCE. The average annual foreign trade of Switzerland is:

	1885-86	1891-96	1901
Imports	$149,000,000	$189,500,000	$223,700,000
Exports	134,000,000	140,000,000	172,600,000

The largest imports are grain, cattle, and other foodstuffs, cotton, coal, iron, petroleum, and groceries. Nearly all the exports are manufactures, such as cheese, wine, silk and cotton goods, watches, fine steel and iron goods (instruments, etc.), machinery, jewelry, lace, embroideries, and straw-plaiting. Manufacturers do not aim to produce large quantities of cheap stuffs, except that cheap watches have, to a great extent, replaced the finer grades. They aim to make a reputation for the excellence and fineness of their goods. Nine-tenths of the import trade and three-fourths of the export trade are with Europe, chiefly with Germany, France, Italy, Great Brit-

ain, and Austria-Hungary. The United States sells very little to Switzerland, but its purchases of cotton embroideries, silk goods, cheese, and other Swiss products are important. Switzerland's trade with the United States in three years amounted to:

	1900	1901	1902
Imports from.....	$250,477	$255,360	$217,515
Exports to.....	17,393,268	15,799,400	17,784,855

TRANSPORTATION AND COMMUNICATION. In the absence of navigable rivers, the international traffic is carried by the railroads. The main arteries are the lines from Lake Constance to Geneva and Basel, and from the north via the Saint Gotthard tunnel to Italy. There are 2490 miles of railroad, and under the law of 1898 the State is acquiring the ownership of the entire system. Switzerland is noted for its admirable wagon roads. Navigation is important on the lakes, where 112 steamboats belonging to fifteen companies were plying in 1901.

BANKING. The 36 banks had, at the close of 1901, paid up capital amounting to $39,155,000; note circulation, $47,610,000; and cash on hand, $23,995,000. Banks of issue are under Government inspection; the notes of the 22 cantonal banks are secured by the cantons, and 10 of other banks by the deposit of securities.

GOVERNMENT. The Constitution of 1848, with the important revision of 1874 and subsequent amendments of lesser importance, constitutes the present fundamental law of Switzerland. (For the methods of amending the Constitution, see REFERENDUM.) The Swiss State is composed of twenty-two cantons, with Bern as the capital. The Constitution vests the executive power in a Federal Council of seven members elected for a term of three years by the two Houses of the Federal Legislature. Any Swiss citizen who is eligible to either branch of the Federal Legislature may be chosen to the Federal Council, except that not more than one member may be chosen from the same canton. It is the custom to choose members of the Council from the membership of the Federal Legislature and to reëlect them continually for a long period of time. The work of administration is divided into seven departments, and one member of the Council is put in charge of each department, but the act of any Councilor is considered to be the act of the Council as a whole. The Council is organized under a president (President of the confederation) and a vice-president chosen by the Federal Legislature from among the Councilors to serve for a term of one year.

The powers and duties of the Federal Council are many and varied. In the domain of legislation it plays an important part, although it has no veto upon the acts of the legislature. In this domain the Council sustains a relation to the legislature somewhat like that of the Cabinet in the parliamentary system of government. It makes an elaborate report to the legislature, and although its members cannot at the same time be members of the legislature, they have access to its sessions, take an active part in the deliberations, introduce legislative proposals, give their opinions upon various measures, and exert a great influence upon the work of legislation. It prepares the budget and advocates its adoption by the legislature, and takes the lead in the discussion of all important measures introduced by the Government. The Federal Council also has a wide power of action in judicial affairs. It has, for instance, the settlement of a large class of administrative controversies which in other Continental countries is intrusted to special administrative courts. It has a large supervisory power over the cantonal administration, particularly when the cantons are engaged in administering federal law. In addition to the above mentioned functions the Council has the other powers usually exercised by a nation's executive.

The strictly legislative powers of the Government are vested in a Federal Assembly (*Bundesversammlung*), consisting of two Houses, viz. the National Council (*Nationalrat*) and the Council of Estates (*Ständerat*). The two Houses hold separate sessions in all legislative matters and joint sessions for the exercise of certain electoral and judicial functions. There is full equality between the two Houses in all matters whatsoever. The Council of Estates is composed of 44 members, or two from each canton. In three cantons which are divided, each half canton chooses one member. The tenure, amount of compensation, qualifications, mode of election, and the relations which they bear to their constituents are matters which the Federal Constitution does not regulate, but are left to the determination of each canton according to its own ideas with the result that the greatest variety of provisions prevails. The terms of members vary from one to four years. The Council of Estates elects its own president and vice-president under the limitation that neither office can be filled from a canton which furnished the president for the session preceding. The National Council, or popular chamber of the legislature, consists of members chosen by direct universal suffrage for a term of three years. The Federal Constitution apportions the members of the National Council according to population on the basis of one representative for every 20,000 inhabitants. In those districts which choose more than one representative the members are chosen on a general ticket. The Council elects its own officers subject to the limitation that the president and vice-president must be chosen from the body of the Council and are ineligible to succeed themselves for an ensuing term. The president, in addition to his vote as a member, has a casting vote in case of a tie. The members of the National Council receive a compensation from the Federal treasury. The Federal Assembly holds two regular sessions annually, beginning in June and December, each lasting about one month. The discussions take place in French, German, or Italian, according to the convenience of the speakers, while all formal readings occur in both French and German. The two Chambers meet jointly to settle conflicts of jurisdiction between the Federal authorities; to grant pardons; and to elect the Federal Council, the Supreme Court, the Chancellor, and the commander of the army. The ordinary legislative power of the Federal Assembly is very wide and extends to many subjects which in the United States are left to the regulation of the States.

The judicial power of the Confederation is vested in a Supreme Court or Federal Tri-

bunal consisting of fourteen judges and a number of supernumeraries elected for a term of six years by the Federal Assembly, which also designates a president and a vice-president of the court for two years. The court is divided into three sections, each of which holds a session in one of the five judicial districts into which Switzerland is divided. The seat of the court is at Lausanne, in the Canton of Vaud. The jurisdiction of the Federal Court in the domain of public law extends to conflicts of authority between the Confederation and the cantons, to disputes between cantons of a public-law nature, and to complaints of the violation of individual constitutional rights. In civil matters of private law its jurisdiction extends to suits between the Confederation and the cantons or between the cantons themselves, or suits against the Confederation or between the cantons and private individuals or corporations. The Federal Tribunal is also a court of appeal from the decisions of the cantonal courts where the amount in dispute exceeds 3000 francs (about $600). Its criminal jurisdiction extends to cases of high treason against the Confederation or violence against the Federal authorities, to offenses against the law of nations, to political offenses which cause disorder and lead to armed intervention, and to certain minor offenses.

For the purposes of local government the political divisions and subdivisions of Switzerland are cantons, districts, and communes. Each canton has its own constitution and local government. With a few exceptions there is a unicameral legislative body called the Great Council, whose members are elected by popular suffrage, as a rule, for a term of three or four years. It enacts laws, votes the taxes, and supervises the administration. In the four cantons of Uri, Unterwalden, Glarus, and Appenzell primary assemblies of all the voters, in many respects like the New England town meeting, take the place of a legislative body. Such assemblies are known as the *Landsgemeinden*. The chief executive authority in all the cantons is a council whose membership varies in number from 5 to 9 in the different cantons. The same may be said of the term of service and the mode of election. At present the members are chosen by popular vote in a majority of the cantons; in the others they are chosen by the local legislatures. In all the cantonal constitutions except that of Fribourg the referendum (q.v.) as a means of legislation has a prominent place. The initiative likewise plays an important part in local legislation. In all the cantons except Geneva constitutional amendments may be initiated by popular petition; and in all except Fribourg, Lucerne, and Valais the same right exists in the case of ordinary statutes.

The cantons are divided into districts. The chief executive and administrative authority in the district is a sort of prefect either popularly elected or chosen by the cantonal Council. A subdivision of the district is called the commune (*Gemeinde*). In some of these the popular town meeting is the chief organ of government; in the others there is a local legislative assembly popularly elected. In all of them the chief executive authority is a small council consisting of a president or mayor and not less than four members.

FINANCE. The Confederation derives most of its revenue from the customs, though considerable income is yielded by the post-office and telegraphs. The alcohol monopoly, amounting in 1901 to about $1,120,000, is divided among the cantons, one-tenth of the amount being used to combat the spread and evil effects of alcoholism. The revenue of the Confederation in 1901 was $20,384,936, and the expenditure was $21,110,618. The public debt amounted on January 1, 1902, to approximately $17,500,000, most of it bearing 3½ per cent. interest. The monetary standard is gold and silver, with the franc as the unit of coinage. Metric weights and measures are used.

DEFENSE. See under ARMIES.

POPULATION. The population, according to the census of December 1, 1900, was 3,315,443. In 1900, 2,319,105 inhabitants spoke German, 733,220 French, 222,247 Italian, and 38,677 Romansh. The total number of foreigners living in the country in 1900 was 392,896. The chief towns, with their populations, in 1901, were: Zurich, 152,942; Basel, 111,009; Geneva, 105.139; Bern, 64,864. The list of the cantons of Switzerland, with areas and populations for 1888 and 1900, is as follows:

CANTONS	Area, sq. miles	Population	
		1888	1900
Aargau	542	193,580	206,498
Appenzell... Ausserrhoden	101	54,109	55,281
Appenzell... Innerrhoden	61	12,888	13,499
Basel... Stadt	14	73,749	112,227
Basel... Land	163	61,941	68,497
Bern	2,657	536,679	589,433
Fribourg	644	119,155	127,951
Geneva	108	105,509	132,609
Glarus	267	33,925	32,349
Grisons	2,773	94,810	104,520
Lucerne	579	135,360	146,159
Neuchâtel	312	108,153	126,279
Saint Gall	779	228,174	250,285
Schaffhausen	114	37,783	41,514
Schwyz	351	50,307	55,385
Solothurn	302	85,621	100,762
Thurgau	381	104,678	113,221
Ticino	1,088	126,751	138,638
Unterwalden... Upper	183	15,043	15,260
Unterwalden... Lower	112	12,538	13,070
Uri	415	17,249	19,700
Valais	2,027	101,985	114,438
Vaud	1,244	247,655	281,379
Zug	92	23,029	25,093
Zurich	666	337,183	431,036
Total	15,975	2,917,754	3,315,443

EDUCATION AND RELIGION. Instruction is compulsory and is rigidly enforced in the Protestant but not in the Roman Catholic cantons. The pupils number nearly 600,000, of whom 471,713 were in the primary schools in 1900. Among the famous institutions are the Universities of Zurich, Bern, Geneva, and Fribourg, the Academies of Geneva and Lausanne, and the "Federal Polytechnic" at Zurich, which attracts pupils from all parts of Europe. In religion there is complete liberty of conscience. About three-fifths of the inhabitants are Protestants, nearly all the remainder being Roman Catholics.

ETHNOLOGY. Such human remains of the prehistoric Swiss as have been found in their lake-dwellings (q.v.) ally the ancient people with the short-headed Celtic or Alpine race. Racially Switzerland is now overwhelmingly Alpine or Celtic (index, 83.8; Romansh 85), especially

in isolated portions, with local invasions of northern and southern types. Great confusion is caused by the conflict between racial characters and environmental influences. Especially in stature is this true, the Teutonic element being shorter instead of taller.

HISTORY. In Roman times the country was inhabited by two races—the Helvetii, supposed to have been Celts, in the northwest; and the Rhætii, who were said to be of common stock with the Etruscans, in the southeast. The Helvetii, having migrated into Gaul, were conquered by Julius Cæsar in B.C. 58, who forced the remnant of them to return to their homes, and before the close of the century the Rhætians were subdued by the armies of Augustus. When the German invasions took place, the Alemanni took possession of the country east of the Aar, while the Burgundians settled in Western Switzerland. About the close of the fifth century the Alemanni were conquered by the Franks and their territory became a part of the Frankish dominion. Another Teutonic people, the Ostrogoths, took possession of the part of the country occupied by the Rhætii, which nearly corresponded to Grisons, but their rule was of short duration. The Burgundians embraced Christianity about the end of the fifth century; the Alemanni retained their old pagan creed until the seventh century, when the band of Irish monks which had entered Gaul under Saint Columban (q.v.) came among them, converted the people in vigorous fashion, and founded abbeys and churches, which survive to our own time. Switzerland made great progress under the rule of the Franks. After the dissolution of the great Carolingian realm the bulk of Switzerland was included in the Duchy of Alemannia, which became part of the German Kingdom, while the southwestern portion of the country was included in the Kingdom of Transjurane, Burgundy. In 1033-34 this Burgundian portion passed under the rule of the German emperors, so that from this time the whole of Switzerland belonged to the Holy Roman Empire. In the early part of the Middle Ages feudalism flourished in the Swiss highlands even more than elsewhere. In the twelfth century the dukes of Zähringen rose to great power in Switzerland. They did much to check civil wars and to promote the prosperity of the towns. In 1178 they founded Fribourg and in 1191 Bern. On the extinction of the line of Zähringen (1218) their allodial possessions passed to the counts of Kyburg, while a number of cities were released from feudal overlordship. In the latter part of the thirteenth century the counts of Savoy extended their domination into Western Switzerland. At this time the counts of Hapsburg became a great power in the land, and in 1264 the house succeeded to the bulk of the possession of the counts of Kyburg. At this time there were a large number of petty sovereignties in Switzerland. Prominent among the ecclesiastical princes were the bishops of Basel and Geneva and the Abbot of Saint Gall. The great towns were united in self-defense, and many of them obtained charters as free Imperial cities. The Hapsburg rule soon became burdensome and tyrannical, and the resistance which opened the long struggle that was to end in Swiss independence began in the three Forest Cantons—Uri, Schwyz, and Unterwalden. Uri received a special charter of liberties from the Emperor Frederick II. in 1231 and Schwyz in 1240. They had leagued themselves together in behalf of the Emperor somewhat later. Thus they were accustomed to the idea of a mutual league when after the death of the Emperor Rudolph they sought to resist the Hapsburgs. In 1291 they allied themselves into a 'perpetual league,' which came to be known as the Eidgenossenschaft. Subsequently they entered into an alliance with Zurich and the coalition of which it was the centre. Unterwalden received a charter similar to that of its associates from the Emperor Henry VII. In 1315 hostilities opened between Frederick of Hapsburg and the Eidgenossen, and the latter won the decisive battle of Morgarten (q.v.). To the period preceding this victory belongs the legend of William Tell. The Forest Cantons then renewed their pact by a fundamental agreement which was for five centuries the basis of the political life of independent Switzerland. Lucerne (1332), Zurich (1351), Glarus and Zug (1352), and Bern (1353) entered the confederation. Fresh wars followed with Austria, whose power in Switzerland was shattered by the victories of the confederates in 1386 at Sempach and in 1388 at Näfels. In 1415 the people of the cantons became the aggressors, invading Aargau and wresting it from Austria. Half a century later they made themselves masters of Thurgau. Swiss independence clashed with the ambitions of Charles the Bold of Burgundy, and the invincible prowess of the Swiss mountaineers shone forth when they were assailed by that powerful monarch. In 1476 they overthrew his armies at Granson and Morat, and it was with the aid of Swiss mercenaries that René of Lorraine overwhelmed Charles the Bold at Nancy in 1477. In 1481 the towns of Fribourg and Solothurn were admitted into the confederacy. In 1499 the Emperor Maximilian I. made a final attempt to bring Switzerland once more within the bounds of the Holy Roman Empire. He sought to draw men and supplies from the inhabitants for his Turkish war, but in vain. He was defeated in six desperate engagements. Basel and Schaffhausen (1501) and Appenzell (1513) were then received into the confederation, and its true independence began. The abbacy of Saint Gall and the cities of Saint Gall, Mülhausen, and Bienne became associated States with a vote in the Diet. Geneva, Neuchâtel, Valais, and Grisons also became associated States, but without a vote. In the early part of the sixteenth century the Swiss soldiers, who had become the most famous infantry in Europe, played a great, if not glorious, rôle as mercenaries in the Italian wars. After fighting successfully on the side of Milan against the French they suffered a terrible defeat at the hands of Francis I. at Melegnano in 1515. In 1516 they concluded the so-called Perpetual Peace with France, after which they fought on the French side. In the course of these wars a number of Italian towns and districts (in the present Canton of Ticino) were annexed to Switzerland.

The Reformation (q.v.), which was inaugurated by Zwingli in 1519, brought dissension among the confederates. Zurich in 1523 adopted Zwingli's opinions, and was followed by Bern and other cantons of the north. The Forest Cantons remained attached to the Church of Rome. War

broke out in 1531 between the Catholics and Protestants, and a small body of Zurichers was defeated at Kappel. Zwingli, who was with them as their chaplain, was slain. In 1536 Bern wrested the Pays de Vaud from the dukes of Savoy and annexed it to its own territory. In the same year Calvin settled at Geneva, which had succeeded in emancipating itself completely from the jurisdiction of Savoy and of its bishop, and the reformed doctrines spread throughout Western Switzerland. During the Thirty Years' War Bern, which had become, since the conquest of Vaud, the leading canton, and Zurich, contrived to maintain the neutrality of Switzerland; and in the Peace of Westphalia, in 1648, the country was formally declared to be wholly independent of the German Empire.

The complex fabric of the Swiss Confederation, with the division into two hostile religious camps, the relation between governing cantons and subjected districts, the selfish assertion of local and class interests, and the absence of any firm bond of union, was not conducive to a healthy political development. The constitution of the larger cantons became more and more aristocratic. In Zurich, Schaffhausen, and Basel the governing councils were elected by the corporations; and in Bern, Fribourg, Solothurn, and Lucerne a few families had acquired permanent rule. The French Revolution had its effect in Switzerland as elsewhere. In 1798 the country was occupied by the French, who were aided by the dissensions between the democrats and aristocrats. The old cantonal system was abolished and the Helvetic Republic was organized. In 1803, at the dictation of Napoleon and under the Act of Mediation, the cantonal system was reestablished, with nineteen cantons, six new ones being constituted—Saint Gall, Grisons, Aargau, Thurgau, Ticino, and Vaud. After this Switzerland enjoyed peace under an orderly government and began to recover prosperity. The Congress of Vienna (1814-15) recognized the independence of Switzerland and her perpetual neutrality and the inviolability of her territory were guaranteed by the great Powers. The new Confederation was divided into twenty-two cantons (three new cantons, Geneva, Valais, and Neuchâtel, being constituted), each of which was represented in a diet, which was appointed to hold its annual meetings alternately at Bern, Zurich, and Lucerne. The old abuses, however, which had crept into the constitutions of the cantons were revived, and representation in most of them became based on property qualifications. Officials, the aristocracy, and the clergy joined to oppose innovations, and succeeded in doing so until the Revolution of 1830 in France. From that year until 1848 Switzerland passed through a long crisis. There was strife between the democratic and aristocratic elements, and then between the Catholics, who in some of the cantons retained ancient special privileges, and the Protestants, who formed a majority of the Swiss people. In Aargau a struggle took place between the Liberals and the Ultramontane Party, which was settled by an unsatisfactory compromise. In Valais, where universal suffrage had put power into the hands of the reactionary party, a war took place, in which this party was victorious. It then ruled with a strong hand, and forbade Protestant worship within the canton. In Lucerne the Ultramontane Party so persecuted its political opponents that the latter were compelled to leave the canton. In 1844 a proposal was made in the Diet to expel the Jesuits, the chief object of Protestant attack; but that body declined to act. The Radical Party then determined to resort to force; they organized bodies of armed men, called "free corps," which invaded the Catholic cantons, but were defeated. The Catholic cantons then formed a league, named the Sonderbund, for defense against the free corps. There was a general clamor for its suppression, but in the Diet only 10½ votes out of 22 were in favor of that measure. The ruling party in Geneva had been with the majority, and this conduct led to a revolution in that city. One vote was thus gained against the Sonderbund. Saint Gall added another; and a majority in the Diet in 1847 declared the illegality of the Sonderbund, and decreed the expulsion of the Jesuits. The Federal forces under General Dufour defeated those of the Sonderbund; the leagued cantons were made liable for all the expenses of the war, the Jesuits were expelled, and the monasteries were suppressed. An attempt was made by diplomatic notes to intimidate the Swiss Government, but the revolutions of 1848 prevented further interference. This same period of civil strife was also one of intellectual and material development. The results of these stormy but profitable years were seen in part in the Constitution of 1848, which bound the Confederation more firmly together and gave it at last an efficient government. This Constitution subsisted until 1874, when the believers in a stronger federal government won a step in that direction. The Constitution of 1874 has been since amended in some of its details. In 1891 the six hundredth anniversary of the 'Perpetual League' was celebrated by the Swiss with great enthusiasm. The history of Switzerland for the past quarter of a century has been very uneventful, though marked by a steady material, intellectual, and political growth.

SWIV'ELLER, DICK. A lively young man in Dickens's *Old Curiosity Shop*, very flowery in language and untidy in dress. He finally marries 'the Marchioness.'

SWORD (AS. *sweord*, OHG. *swert*, Ger. *Schwert*, sword; of uncertain etymology). In its general sense, every steel weapon of offense or defense larger than the dagger or poniard; in modern military usage the term *sword* is used to describe the infantry or straight weapon, and *sabre* for the slightly curved weapon of the cavalryman. Although the distinction is clearly marked in Germany by the employment of *Degen* for the straight sword and *Säbel* for the curved weapon, the custom with other nations is to employ a single word for both varieties. The sword always has been, and is at present, a personal weapon; so much so that in the prose and poetry of all nations it is often endowed with human as well as superhuman qualities. To surrender the sword has always been a token of submission, and the breaking of it a most impressive ceremony of degradation, while to kiss the sword is even to-day with Orientals the highest form of oath and homage. The first sword was undoubtedly of hard wood, and judging from the widely scattered area in which it has been proved to have been known, its employment must have been practically spontaneous among all the peoples whose stage of civilization rendered possible its use. Wooden swords were part of the equipment of the Indians of Virginia, according to the statement of Captain John Smith. Greek literature refers more frequently to the spear and bow than to the sword, as is the case with the Roman and Hebrew writings. According to the testimony of the Greek works of art, the leaf-shaped blade sword was the one used by the Greeks in historical times, although the Greeks, almost alone of the ancient peoples, held the sword in but slight estimation. The ancient sword was usually worn on the left side suspended by a belt from the shoulder, although it was sometimes slung more forward, bringing the hilt in the front, or else suspended from a girdle around the waist. With the Egyptians the sword of bronze was carried in its leather scabbard in front of the body, and thrust in the sword belt in a sloping direction from right to left. The Assyrians seem to have possessed the weapon most nearly approaching the sword of to-day. It was straight and narrow and apparently designed for thrusting as much as for cutting. The pointed sword of the Roman legionaries was invariably successful when opposed to the pointless weapons of their enemies. On the other hand, most Asiatic nations to this day continue to use the sword as a cutting weapon, its curved shape usually preventing any use of the point. Thus the swords, military and civil, of to-day may be said to be descended from the European straight sword and the Eastern *scimitar* or *tulwar*. Under FENCING will be found the history of the sword up to the present day.

Asia has been more prolific in the matter of variety of blades than has Europe; for instance, the *yataghan* of the Mohammedan races with its double curve is a compact and formidable weapon, as also is the *kukri* of the Gurkhas, which resembles the *yataghan* except that it is considerably broader in the blade. The *pată*, a long straight-hilted sword, is found in the south of India, while in the north the *katár*, a broad-bladed weapon with a cross-bar handle, was for a long time in favor. The Japanese swords are many in number and characteristic to a degree of the Japanese people. They may be classified as two-edged swords called *tsurugi*, and one-edged swords called in general *katana*. The *tsurugi* is the primitive weapon of Japan, and is now rarely met with except as an ornament in temples. It was from 28 to 40 inches long and about 2½ or 3 inches wide, and in the middle up to ⅜ of an inch thick. It ended in a sharp point and often thickened and broadened toward the point. It was evidently designed more for cutting than for thrusting. The *katana* or one-edged sword is also a cutting rather than a thrusting weapon, but is a much more handy sword than the *tsurugi*. The various varieties of the *katana* are named according to their length, which is measured from the guard (at the inner end) to the hilt of the point, as: *Lachi; katana proper; wakizashi; tautô;* and many others. The *katana* proper is from 2 feet 6 inches to 2 feet 9 inches long, and is the common straight sword of the Japanese military class. The *tautô* or short sword was the weapon allowed to be worn by the tradesmen, and all others not allowed to wear the *katana*. The *kuwaiken* is a small sword worn by the ladies of the military class.

The modern military sword of all civilized nations is so constructed as to combine all the advantages of cutting and thrusting. The thrust is regarded as by far the most effective attack, but as it demands considerable skill and coolness, and as the average soldier (who in modern campaigns will in the majority of instances have been hastily taken from civil life) cannot be always counted upon to remember his training and will very naturally use the cut, it has led to the compromise above described. A good sword is required to be sufficiently elastic to permit of its being bent, or to resist a heavy blow without breaking or other injury, and also to be strong enough to deliver a thrust without bend-

ing too much. Equally important is the requirement that it be as light as possible, consistent with the strength required, and that it be well balanced. The military blades of to-day are all closely similar in design. They are nearly straight, but sufficiently heavy toward the point to enable the soldier to deliver a very effective cut. The only exception is the sword adopted by the French Government in 1899, which is a long sword designed only for thrusting. It is 35 inches in length of blade from hilt to point, and weighs 2 pounds 6 ounces without the scabbard, which latter is made of steel, with a wood lining. The German cavalry sword is 32½ inches long from hilt to point, and weighs 2 pounds 8½ ounces without the scabbard. The scabbard, like that of the French and British, is of steel with wood lining. The British cavalry officer's sword measures 35 inches from hilt to point, and weighs without the scabbard 2 pounds; while the sword of the trooper measures 33½ inches, and is 2 pounds 10¼ ounces in weight. The British infantry sword (officer's) measures 32½ inches from hilt to point, and weighs, without scabbard, 2 pounds 3 ounces. In the United States Army the sword proper has been abolished and a single form of sabre is now worn by all officers. These are issued in lengths of 30, 32, and 34 inches. The troopers of the United States cavalry have a sabre which is designed for both cutting and thrusting, and differs from the light artillery sabre, which is intended for cutting only and is more curved. In addition to the article FENCING, already mentioned, the reader is referred to the articles CAVALRY; TACTICS, MILITARY.

SWORD, ORDER OF THE. A Swedish military order of merit, with seven classes, founded in 1522 and renewed by Frederick I. in 1748. The decoration is a white cross of eight points, the arms separated by golden crowns. The blue medallion shows a bared sword surrounded by three crowns. The reverse bears a sword with a laurel wreath and the legend *Pro Patria.*

SWORD DANCE. A dance in which the use of a sword plays the characteristic part. Such dances, held in military attire, and serving as exercises of youth, were probably a feature in the life of all ancient peoples. In Greece a dance of this character was known under the name of Pyrrhic, and in Athens such a performance was said to have been instituted by Athena. Tacitus describes the youths of Germany as dancing naked over a bare blade, and fifteen centuries later a particular form of the sword dance was described by Olaus Magnus as belonging to Denmark. This special dance was widely diffused, and has survived in Germany, England, and Scotland. In it the number of performers was commonly six, with a leader; the movements were various, consisting of a march with weapons erect, directing them toward the centre of the ring, grasping the neighbor's blade by the hilt and point, forming the swords into a shield or rose and dancing with them in that form, leaping over and under the brands, and the like.

SWORDFISH. One of several fishes having an elongated snout, serviceable as a weapon; specifically, the single representative of the family Xiphiidæ, related to the mackerels and common in the warmer parts of the Atlantic and occasional in the Pacific Ocean. This fish has a round, very muscular body (see Plate of SPEARFISH AND SWORDFISH), with large fins and a crescentic tail of extraordinary size and power, so that it is able to move with extreme speed and force. As the young grow, the fore part of the body and the head increase steadily in girth in proportion to the posterior parts, and the upper jaw grows more and more elongated until it finally forms a flattened, sharp-edged 'sword' composed of the consolidated vomer, ethmoid and premaxillary bones, and coated with a finely granulated hide. This weapon is about half as long as the body, and becomes so strong that it may be driven far through the planking of a rowboat or even a sailing vessel, as has repeatedly happened, probably by accident. The swordfish reaches its largest size off the coast of New England, where in midsummer it comes near shore in pursuit of the schools of herring, mackerel, menhaden, and other gregarious fishes upon which it mainly feeds. A swordfish finding such a school pushes into its midst from beneath, and, striking right and left with its sword, kills or disables dozens of victims. The average size in the Atlantic is about seven feet in total length and 250 pounds in weight, but there are authentic records of fish more than twice that size. The flesh is of excellent flavor, and the capture of a swordfish is reckoned fine sport. Their spawning habits are little understood; and where they spend the winter, when they disappear from the American coast, is unknown.

Several other large related fishes are called 'swordfish,' among them the 'sailfish' and 'spearfish' (qq.v.) of the family Istiophoridæ; the large handsome 'papagallo' (*Nematistius pectoralis*) of the Pacific coast of tropical America; and the cutlass-fish (q.v.). The best general account of the swordfish and swordfishing is by Goode, *Fishery Industries*, sec. i. (Washington, 1884).

SWORDFISHING. The catching of swordfish is pursued in summer both for profit and sport off the coast of New England, and especially in the neighborhood of Nantucket, and is often the occasion of exciting incidents. Small swift vessels are employed, provided with a short bowsprit, at the outer end of which is set a small platform and a strong iron stanchion surmounted by a circular horizontal band at the height of a man's waist. The fisherman, standing within this contrivance, with a connecting strap buckled behind him, is held safely in spite of the pitching of the vessel, while both his arms are left free. A swordfish having been sighted at the surface, where it is feeding upon menhaden or some similar prey, the schooner bears down upon it until the fisherman is able to hurl a barbed spear, or a heavy grain, into its body. To this spear a line is attached, fastened inboard; and if a successful strike is made the crew gradually haul the struggling fish near enough to be knocked on the head and disabled. As the swordfish is big and strong, and is armed with formidable weapons in his 'sword' and his powerful tail, much strength, skill, and agility are required to overcome and secure it; and the sport is justly regarded as exhilarating and courageous in the extreme. Consult: Goode, *Fishing*

Industries, sec. i. (Washington, 1884); Halder, *Marvels of Animal Life* (New York, 1885).

SYB'ARIS (Lat., from Gk. Σύβαρις). A celebrated Greek colony in Magna Græcia (q.v.). It was situated in northeastern Bruttium, between the river Crathis (*Crati*) and Sybaris (*Coscile*), about three miles from the Tarentine gulf. It was founded by Achæans and Trœzenians at an early period in the colonization of Magna Græcia, and it soon acquired control of territory extending entirely across the peninsula. Sybaris was a great mercantile city, with strong democratic tendencies. The wealth and luxury of the inhabitants became proverbial. Of the history of the city almost nothing is known, but during the sixth century B.C. it had attained a circumference of more than five miles, and ranked with Miletus as one of the most powerful and wealthy of Grecian cities. The party strife which disturbed so many of the Greek mercantile communities raged here also, and toward the end of the century we find the city in the hands of a tyrant, Telys, supported by the popular party. A Crotonian noble who married Telys's daughter was exiled by his townsmen, and they also gave asylum to a large body of the banished nobles of Sybaris. The refusal of a demand for their surrender led to a war between the two cities, in which the Crotonians, in spite of inferior numbers, won a great victory, which was followed by internal strife in Sybaris, leading to the easy capture of the city (c.510 B.C.). The victors razed it to the ground and turned the bed of the Crathis over the site. The few survivors withdrew to their colonies, Scidros and Laos, on the west coast. Excavations in 1879 and 1888 have determined the site of the ancient city, but yielded little else of interest.

SYBEL, zē'bĕl, Heinrich von (1817-95). A German historian, born at Düsseldorf, December 2, 1817. He studied four years at Berlin and at Bonn, and in 1841 published his first work, the *Geschichte des ersten Kreuzzugs*. In 1844 he was made professor extraordinary at Bonn and two years later went to Marburg as professor in ordinary. It was there that he wrote his *Geschichte der Revolutionszeit von 1789 bis 1795* (1853-58), the most important of his works with one exception. In 1856 he became professor at Munich, where he instituted the historical commission of the Royal Bavarian Academy and founded the *Historische Zeitschrift*, and in 1861 was appointed professor at Bonn. He was made director of Prussian archives in 1875 and thus had access to the most valuable material for his chief work, *Die Begründung des deutschen Reichs* (Munich, 1889-94; trans. by Perrin, New York, 1890-97). Sybel was from 1862 to 1864 and from 1874 to 1880 a member of the Prussian Diet, and in 1867 was elected to the Constituent Reichstag of the North German Confederation. He died at Marburg, August 1, 1895. —His son Ludwig (1846—) is an archæologist, professor at Marburg since 1877, and author of: *Die Mythologie der Ilias* (1877); *Kritik des ägyptischen Ornaments* (1883); *Weltgeschichte der Kunst im Altertum* (2d ed. 1902), and others.

SYC'AMORE. The county-seat of Dekalb County, Ill., 52 miles west by north of Chicago; on the Chicago Great Western and the Chicago and Northwestern railroads (Map: Illinois, D 2). It is in a farming section, but is important rather for its manufactures, which include farm implements, gray iron castings, insulated wire, canned goods, etc. The water works are owned by the municipality. Population, in 1890, 2987; in 1900, 3653.

SYCAMORE, or **SYCOMORE** (OF., Fr. *sycomore*, from Lat. *sycomorus*, from Gk. συκόμορος, *sykomoros*, mulberry-tree, from σῦκον, *sykon*, fig + μόρον, *moron*, μώρον, *mōron*, black mulberry), *Ficus*. A genus of generally large, long-lived trees of the natural order Moraceæ, mostly natives of Africa and Asia. The Egyptian sycamore (*Ficus sycomorus*), supposed to be the sycamore of the Bible, is a large spreading tree often planted for shade in Egypt and Western Asia, where it is abundant in forests. The figs are top-shaped, and grow in clustered racemes on the trunk and oldest branches. They are sweet, well-flavored, and somewhat aromatic. The sycamore of Western Europe is a species of maple (q.v.); those of North America are various species of plane (q.v.).

SYCAMORE INSECTS. The sycamore or plane tree is comparatively free from insect attack, for although several caterpillars feed upon the leaves of the tree, none seems specifically confined to it. The leaves sometimes turn brown and fall from the attacks of colonies of one of the lace-bugs (*Corythuca fimbriata*), and the seed-balls are attacked by a true bug (*Melanochilus numideus*), which punctures the leaves and passes the winter in a half-grown condition thrust down between the seeds in the ball. Only one borer seems specifically confined to this tree, but *Chalcophora campestris* is found burrowing into dead limbs and trunks, and may hasten the death of an otherwise diseased tree. Consult Packard, *Insects Injurious to Forest Trees* (Washington, 1890).

SYCOSIS (Neo-Lat., from Gk. σῦκωσις, *sykōsis*, fig-like excrescence on the flesh, from σῦκον, *sykon*, fig). A skin disease characterized by an eruption of pustules or papules, each one pierced by a hair, generally limited to the bearded face. It is, in common with *impetigo faciei* and *tinea barbæ*, called 'barber's itch.' It is caused by the entrance into the hair follicles of a variety of staphylococcus, either albus, aureus, or citreus. Acne or eczema may be mistaken for it. Zinc, oil of cade, carbolic acid, ichthyol, sulphur, and betanaphthol are all recommended for its relief.

SYDENHAM, sĭd'en-am. A residential section and Parliamentary sub-district of Lewisham Borough, metropolitan London, 8 miles southeast of Saint Paul's Cathedral (Map: London and vicinity, F 8). It is of world-wide celebrity in connection with the Crystal Palace (q.v.), which was reërected here in 1854. Population, in 1891, 34,100; in 1901, 43,630.

SYDENHAM, Thomas (1624-89). A great English physician, born at Winford Eagle, educated at Magdalen Hall, Oxford, at All Souls' College, and at Montpellier, France. He received his degree in medicine from Cambridge, and in about 1650 established himself in practice in London, and soon became the foremost physician of his time. Although his name is inseparably con-

nected with our present knowledge of many diseases, he is especially to be remembered as the one who introduced cinchona in the treatment of malaria, and who first differentiated scarlatina, classified chorea, and expounded gout. A collection of his works was published in English (1785); and the Sydenham Society of London, founded for the purpose of printing meritorious medical works, put forth as its first issue his complete works in Latin in 1846, and in English in 1848. Consult Latham's *Memoir* (London, 1848).

SYDNEY. The capital of New South Wales and the oldest city in Australia, on the southern shores of Port Jackson; latitude 33° 52′ S., longitude 151° 13′ E. (Map: New South Wales, F 3). It is situated about 8 miles from the sea, and the whole bay round which the city is built forms a fine harbor, where the largest vessels can safely anchor. Its bold and rocky shores present a succession of picturesque and beautiful landscapes. The narrow entrance is called the 'Heads,' and is marked by a lighthouse. The Fitzroy dry-dock, originally intended for vessels of the royal navy, can accommodate vessels of the largest size. The city is defended by modern forts and batteries, and is the chief station of the Australian navy. The neighborhood of Sydney is surrounded by park-like grounds, and gardens of orange trees, bananas, and numberless semi-tropical plants. The suburbs include 41 municipalities, the chief of which are Balmain in the west; Newton, Redfern, Marrickville, and Waterloo in the south; Paddington, Randwick, Woolhara, and Waverley in the east.

The climate of Sydney is, upon the whole, temperate and healthful. The sandstone rock upon which the city is built affords a valuable material for building. The streets in the older parts of the town are narrow and irregular; in the newer portions they are modern, and the size and style of the buildings are not behind those of the principal towns of Europe. The University of Sydney stands on a commanding height. There are two suffragan colleges in connection with the university—that of Saint Paul's, belonging to the Church of England, and Saint John's, erected under the auspices of the Roman Catholic community. The metropolitan Cathedral of Saint Andrew is a handsome building in the later Perpendicular style of architecture, and the Roman Catholic Cathedral of Saint Mary is also a fine structure. Noteworthy are the residence of the Governor, the museum, the National Art Gallery, the exchange, the custom-house, the town hall, the new post-office, the public grammar school, and the theatres. Sydney has several mechanics' institutes.

There are fine botanical gardens, and a number of public parks, of which Hyde Park is the chief. Water is brought from a point on the Nepean River, 63 miles distant, and stored in a large reservoir at Parramatta. The water-works, abattoirs, and street railways are municipal property. The manufactures comprise wagons, glass, pottery, boots and shoes, carriages, stoves, and tobacco, and there are car-shops, distilleries, and breweries. At various points within a radius of from 30 to 100 miles large quantities of coal are mined for colonial consumption as well as for export. Its central position makes Sydney the permanent emporium of the British dependencies in the Southern Hemisphere. It maintains its position as the exclusive outlet for the productions and commerce of extensive pastoral and mineral districts on the northwest, west, and southwest.

The first party of British settlers (convicts) that reached Australia were landed at Botany Bay on January 20, 1788. The spot which had been selected being found unsuitable, it was abandoned a few days afterwards, and the infant settlement was transferred to a point about 7 miles farther to the north, the place where Sydney now stands. The choice of the new locality was chiefly determined by the circumstance of a stream of fresh water found there, flowing into the deep inlet known as Sydney Cove, one of the numerous bays into which the basin of Port Jackson is divided. After the abolition of convict transportation the growth of Sydney was rapid. The installation here, on January 1, 1901, of Earl Hopetoun as first Governor-General of the Australian Commonwealth consummated the federation of Australia. The population of municipal Sydney in 1901 was 111,801; of the city with its suburbs, 488,968.

SYDNEY, ALGERNON. An English statesman. See SIDNEY, ALGERNON.

SYDOW, zē'dō, EMIL VON (1812-73). A distinguished German cartographer, born at Freiberg, Saxony. He entered the Prussian army in 1829, taught geography, and in 1838 began to publish his excellent school-room maps. Detailed to Berlin in 1843 as a member of the Military Examination Committee, he was subsequently intrusted with the geographical lectures at the Military Academy, which he resumed in 1860, having in the meanwhile lived retired at Gotha since 1855. Attached to the great general staff, he was made director of the geographic-statistical department in 1867 and colonel in 1870. His cartographic work, nearly all translated also into foreign languages, comprises: *Methodischer Handatlas für das wissenschaftliche Studium der Erdkunde*, 30 maps (4th ed. 1870); *Schulatlas in 42 Blättern* (32d ed. 1880); new ed. by Wagner, entitled *Sydow-Wagner, Methodischer Schulatlas*, 63 main and 50 accessory maps (10th ed. 1902); *Oro-hydrographischer Atlas*, 25 maps; and others. He also contributed many articles to various periodicals, notably the reports "Ueber den kartographischen Standpunkt Europas," to *Petermanns Mitteilungen* (1857-72), and created the valuable book of reference *Registrande der geographisch-statistischen Abteilung des Grossen Generalstabs* (Berlin, 1870-83).

SYENE, sī-ē'nē. The ancient name of Assuan (q.v.), a town of Egypt.

SYENITE (Lat. *syenites*, from *Syene*, from Gk. Συήνη, a locality in Upper Egypt). An igneous rock of granitic texture, composed essentially of alkali feldspar and mica, hornblende, or augite (mica syenite, hornblende syenite, augite syenite). Its average composition is: silica, 59 per cent.; alumina, 17 per cent.; oxides of iron, 7 per cent.; magnesia, 37 per cent.; oxide of lime, 5 per cent.; oxide of sodium, 4 per cent.; oxide of potassium, 5 per cent. From granite syenite differs in containing little or no free silica (quartz).

SYKES, sīks, GEORGE (1822-80). An American soldier, born at Dover, Del. He graduated at West Point in 1842, served in the Seminole and Mexican wars, and was brevetted captain for gallant conduct at Cerro Gordo. He fought in the first battle of Bull Run, as a major in the Federal army; was commissioned brigadier-general of volunteers in September, 1861, took part in the Peninsular, in the second Bull Run, and in the Antietam campaigns; was commissioned major-general of volunteers in November, 1862; fought at Fredericksburg and Chancellorsville; and commanded the Fifth Corps at Gettysburg. In March, 1865, he was brevetted brigadier-general in the Regular Army for his services in the battle of Gettysburg and major-general in the Regular Army for his services during the war. He was mustered out of the volunteer army in January, 1866, but remained in the Regular Army first as lieutenant-colonel and then as colonel until his death in 1880. A monument has been erected in his honor at West Point.

SYKES, OLIVE (LOGAN) (1839—). An American actress and author, born in New York. In 1864 she appeared at Wallack's Theatre, New York, in *Evelcen*, a play of her own composition; but retired from the stage in 1868, and devoted herself principally to lecturing and writing in behalf of the woman's rights movement. Her later publications include *Women and Theatres* (1869); *Before the Footlights and Behind the Scenes* (1870); and the comedy *Surf, or Life at Long Branch*.

SYL'LABUS ERRO'RUM (Lat., catalogue of errors). A document published by Pius IX. in 1864, appended to the encyclical *Quanta cura*, condemning eighty doctrines which it calls "the principal errors of our times." They are classed under various heads: pantheism, naturalism, and absolute rationalism; moderate rationalism; indifferentism and latitudinarianism; socialism, communism, secret societies, Bible societies (considered from the point of view as Protestant proselytizing organizations), and clerico-liberal societies; errors concerning the Church and her rights; concerning civil society; concerning natural and Christian ethics; concerning Christian marriage; concerning the temporal power of the Pope; and errors connected with modern liberalism. The text of the document and an English translation are given in Schaff, *Creeds of Christendom* (New York, 1877-78). The Syllabus gave rise in England to a famous controversy between Gladstone and Newman. Consult Gladstone, *Vaticanism* (London, 1875); Newman, *Letters to the Duke of Norfolk* (ib., 1875).

SYLLOGISM (Lat. *syllogismus*, from Gk. *συλλογισμός*, reasoning, conclusion, from *συλλογίζεσθαι*, *syllogizesthaĭ*, to infer, conclude, from *σύν*, *syn*, together + *λογίζεσθαι*, *logizesthai*, to reason, from *λόγος*, *logos*, word, reason). The name of a logical operation when expressed in a certain form in accordance with the principles of formal logic. When we reason, or get at truth by means of inference, we are said to proceed either inductively (see INDUCTION) or deductively. Deductive reasoning, when fully and methodically expressed, takes the form called the syllogism. 'This thing will sink in water, for it is a stone,' is a deductive argument, but not fully stated; this is called an enthymeme (q.v.). The complete form is, "Stones sink in water; this is a stone; therefore, this sinks in water'—which form is called a syllogism.

To a perfect syllogism it is necessary (1) that there should be three, and no more than three, propositions (see PROPOSITION); these are the conclusion, or the matter to be proved, and two others that are the means of proving it, called the premises. It is also necessary (2) that there should be three, and no more than three, *terms*, namely, the subject and the predicate of the conclusion, and one, called the middle term, which must occur in both premises, being the connecting link for bringing the two other terms together in the conclusion. The *predicate* of the conclusion is called the major term, because it is in its extension (q.v.) the largest of the three; the *subject* of the conclusion is the minor term, as being the smallest in extension. The major and minor terms are called extremes. The three terms appear in the premises in this manner: the major term and the middle term appear in one premise, called the major premise; the middle term and the minor term in the minor premise. In the syllogism above stated, the terms are '(a thing that will) sink in water' (major), 'this thing' (minor), 'stone' (middle); the premises are, 'stones sink in water' (major), 'this thing is a stone' (minor); the conclusion is, 'this thing sinks in water'; (3) one premise at least must be affirmative; (4) if one premise be negative, the conclusion must be negative; (5) the middle term must be distributed (= taken in the whole of its extension) in at least one premise; (6) an extreme, if undistributed in a premise, may not be distributed in the conclusion. Any syllogism which violates any one or more of these six syllogistic rules is invalid. There are two other rules which are derivative: (7) one premise at least must be universal; (8) if one premise be particular, the conclusion must be particular also. Any syllogism which violates either of these rules violates also one or more of the first six rules given above. For the discussion of the question as to the evidence of these canons, see LOGIC.

Categorical syllogistic forms are divided into *figures*, and each figure into *moods*, which are the distinct syllogistic forms, the principle of division being as follows: The figure is determined by the function of the middle term, in the two premises; it may be the *subject* of the major premise, and the *predicate* of the minor (1st figure); the *predicate* in both (2d figure), the *subject* in both (3d figure), the *predicate* of the major and the *subject* of the minor (4th figure). The 4th figure did not belong to the original scheme of Aristotle, and it is usually considered as both unnatural and unnecessary, being only an awkward inversion of the first. The syllogisms of each figure are said to differ in *mood*, or according to the *quality* and the *quantity* of the propositions—that is, according as these are affirmative or negative (quality), universal or particular (quantity).

A conditional syllogism whose conditional major premise presents some sort of alternative is called a *dilemma*. We may have these cases: Either (*a*) alternative consequences may be as-

serted to follow upon a single condition (or combination of conditions) or (*b*) alternative conditions may be asserted to determine a single consequence (or combination of consequences); or (*c*) an alternative may be presented between a condition with its consequence and another condition with its separate consequence. If alternative consequences are asserted to follow upon a single condition, then it is possible to have a valid conditional syllogism either when a minor premise affirms the condition, warranting as conclusion the affirmation of the alternative consequence; or when a minor premise denies conjunctively ('neither—nor') the alternative consequences, warranting as conclusion the denial of the antecedent. If alternative conditions are asserted to determine a single consequence, it is possible to have a valid syllogism when a minor premise either categorically affirms one of the conditions or disjunctively affirms both conditions, in either case justifying as conclusion the affirmation of the consequent; or when the minor premise categorically denies the consequent, justifying as conclusion the conjunctive denial of the conditions. If the major premise presents an alternative between a condition with its consequence and another condition with its separate consequence, a valid syllogism obtains when the minor premise either disjunctively affirms the two conditions, justifying the disjunctive affirmation of the two consequences, or when the minor premise conjunctively or disjunctively denies both consequences, justifying a conjunctive or disjunctive denial respectively of the two antecedents. For bibliography, see books mentioned under LOGIC. See also FALLACY; DILEMMA; CONVERSION; OBVERSION.

SYLPHS (Neo-Lat. *sylpha*, probably from Gk. *σίλφη*, *silphē*, sort of beetle; so called as being a spirit flying in the air). In the fantastic system of the Paracelsists, the elemental spirits of the air, who, like the other elemental spirits, hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul; and when they die, nothing is left.

In common usage, the term 'sylph' has a feminine signification, and is applied to a graceful maiden. How this curious change of meaning occurred is not quite certain; but it is possibly owing to the popularity of Pope's *Rape of the Lock*, which introduced the term into the world of fashion and literature. Consult: Paracelsus's *Liber de Nymphis, Sylphis, Pygmæis et Salamandris et Cæteris Spiritibus* (Basel ed. of Paracelsus's works, 1590).

SYLVANITE. See TELLURIUM.

SYLVESTER. The name of two popes. SYLVESTER I., Pope 314-335. His reign was the first in the new period of Church freedom under Constantine. In his pontificate the Council of Nicæa was held, which he did not himself attend, but sent two legates to represent him. Numerous unhistorical legends, especially concerning his relations to Constantine, have clustered about him; concerning them, consult Döllinger, *Fables Respecting the Popes in the Middle Ages* (Eng. trans., New York, 1872); and see DONATION OF CONSTANTINE. His works are in Migne, *Patrologia Latina*, viii.—SYLVESTER II., Pope 999-1003, Gerbert by name. He was born at Aurillac, in Auvergne, about 935, and at an early age went to Spain, where he made remarkable progress in scientific studies. He became head of the cathedral school at Rheims, which grew to eminence under his direction. In 982 he was made Abbot of Bobbio on the nomination of Otho II., but returned to Rheims, of which, by Hugh Capet's wish, he was chosen Archbishop in 991. Four years later, the deposition of his predecessor having been declared invalid, he went to Magdeburg on Otho III.'s invitation, and accompanied him to Italy, where he remained, becoming Archbishop of Ravenna in 998, and reaching the Papal throne in the following year. He was a strict reformer, and acquired the reputation of the most learned man of his age; he was an adept in mathematics, and in practical mechanics and astronomy, in which his attainments were so amazing to his contemporaries as to arouse a suspicion that he was in league with the devil. The Gubar numerals, the ancestors of our modern numerals and due to the Western Arabs, owe much of their prominence, if not their introduction into Europe, to Sylvester. His writings are reprinted in Migne, *Patrologia Latina*, cxxxix.; also by Olleris (Paris, 1867); his letters, which throw much light upon an obscure period, have been translated into French (Riom, 1847). Consult studies of his life and times by Hock (Vienna, 1837), Axinger (Paris, 1842), Tappe (Berlin, 1869), and Schultess (Hamburg, 1891); also Schultess, *Die Sagen über Silvester II.* (ib., 1893), and the book of Döllinger referred to above.—The name was also borne by two antipopes, SYLVESTER III., who contested the Papal throne with Benedict IX. in 1044, and SYLVESTER IV., who was put up by the Imperial party to oppose Paschal II. in 1105.

SYLVESTER, JAMES JOSEPH (1814-97). One of the foremost English mathematicians of the nineteenth century. He was born in London, of Jewish parents, and received his early education in a Jewish school. He then attended the Royal Institution school in Liverpool, and thence proceeded to Saint John's, Cambridge (1831). As a Jew he was barred from taking a degree, and it was not until the passing of the Tests Act that he obtained his B.A. at Cambridge (1872). He studied at the Inner Temple after leaving Cambridge, and was called to the bar in 1850. Sylvester was appointed professor of natural philosophy at University College, London, in 1837, and was elected fellow of the Royal Society in 1839. In 1841 he was appointed professor of mathematics in the University of Virginia, but soon after (1845) returned to England, where he took up the work of an actuary. In 1855 he became professor of mathematics at the Royal Military Academy at Woolwich, where he remained for 15 years. In 1877 he became the first professor of mathematics at Johns Hopkins University, which position he held for seven years, returning to England to accept the Savilian professorship of geometry at Oxford. He founded

the *American Journal of Mathematics* and was for some years its editor.

Sylvester's contributions were almost exclusively in the form of memoirs, scattered through various scientific journals and the proceedings of various societies. They are devoted chiefly to the theories of algebraic forms (see FORMS), in which he was the recognized leader of the mathematical world. He and Cayley (q.v.) contributed more than any of their contemporaries to the theory of invariants, and he may be said to have practically created the vocabulary of the subject. He also published a work on *Laws of Verse* (1870), a subject in which he always showed an interest. Consult obituary notices in various scientific journals in 1897; and Franklin, *Address Commemorative of Sylvester* (Baltimore, 1897).

SYLVESTER, JOSHUA (1563-1618). An English poet, born in the north of Kent. His life was divided between poetry and trade. He is mainly known for a translation, or rather paraphrase, of the *Semaines* (Weeks), a sacred epic written by the French poet Du Bartas (q.v.). The translation had considerable influence upon Milton. Of Sylvester's original verse, all is forgotten except the beautiful sonnet beginning "Were I as base as is the lowly plaine" (in Palgrave's *Golden Treasury*). Consult his *Works*, ed. A. B. Grosart, "Chertsey Worthies Library" (2 vols., London, 1878).

SYLVESTER DAGGERWOOD. A one-act play by George Colman the younger, produced in 1795, a shorter form of *New Hay at the Old Market*, brought out in the same year. There were only two characters in it, the strolling player whose name is the title, and Fustian, a playwright.

SYLVICULTURE. See FORESTRY.

SYLVIUS. The Latinized name of Jacques Dubois (1478-1555), a French anatomist, born near Amiens. He studied in Paris, and afterwards was a lecturer on anatomy there. His anatomical discoveries and his invention of injection for use in dissection cause him to be remembered. The Sylvian fissure, the Sylvian aqueduct, and the Sylvian artery were named in his honor. His *Opera Medica* were published at Geneva in 1630.

SYMBIOSIS (Neo-Lat., from Gk. *συμβίωσις*, life together, from *σύν*, *syn*, together + *βίος*, *bios*, life.) That condition in which two or more dissimilar organisms live together in an intimate life relation. Various types of symbiosis depend upon the type of relation existing between the organisms, the so-called symbionts.

(1) Mutualistic symbiosis, or mutualism, is that condition in which each party to the symbiosis seems to derive advantage therefrom. This relation has perhaps not been proved to exist in plants, though it seems likely that mutualism exists between the legumes and the bacteria of their root tubercles. Many believe that lichens show true mutualism, the fungus symbiont supplying nitrogenous substances or other materials absorbed from the substratum, and the alga symbiont the carbohydrates.

(2) Antagonistic symbiosis, or parasitism, is that condition where one symbiont gains at the expense of the other. There are many illustrations of this in nature. For example, the parasitic fungi and seed plants may be regarded as securing food from their host plants, but not giving an equivalent in return, as is the case in perfect mutualism.

(3) A somewhat intermediate condition is illustrated by contingent symbiosis, or helotism (q.v.). Some writers hold that lichens illustrate this type, the idea being that there is not a mutual exchange between the alga and the fungus symbiont. The fungus is supposed to gain, but the alga is supposed neither to lose nor gain.

Symbiosis may be more or less intimate. In conjunctive symbiosis the symbionts are blended together so as to form a single body, as best illustrated by the lichens. In disjunctive symbiosis the symbiosis is more temporary, or the symbionts are less completely blended, as illustrated by ectotropic mycorrhizas.

Relations which are, perhaps, not to be regarded as symbiosis, but which nevertheless bear a close similarity to it, are frequently found. Saprophytism differs from parasitism only in that the host plant, so to speak, is dead. Recently a new life relation has been recognized, such as is found in the Indian pipe (Monotropa); in which case there is a root fungus which derives its food materials saprophytically from the soil. Monotropa, not being a green plant, gets nearly all of its food material from the fungus. Hence the relation of the two organisms taken together is saprophytism. The mutual relation of the pair is, however, symbiosis, and the whole relation may be called symbiotic saprophytism. This term may be applied to all of the mycorrhiza plants. By some authors lianas and epiphytes have been regarded as having symbiotic relations with the supporting plants, but the relation is not at all intimate, since they probably get only mechanical support. Kerner held a still broader view of symbiosis, applying this term, for instance, to the herbaceous shade plants of the woods, which are unable to grow unless shaded by the trees.

Among animals forms of symbiosis are to be found. An example of social symbiosis is the case of a polyp (Epizoanthus) or a sea-anemone (Adamsia), which grows on the shell inhabited by a hermit-crab. Klebs states that when the crab changes its shell it seizes the anemone and carries it off to its new home. The term *physiological symbiosis* may be applied to cases among the lowest organisms where certain algæ (Zoöxanthellæ) often live in Radiolaria (q.v.), while similar green and yellow plants inhabit the stomach epithelium of many actinians, corals, and worms. As Hertwig says, the Zoöxanthellæ are nourished by the carbon dioxide which is formed by the animal tissues, and breathe out oxygen, which in turn serves as food for the animal. They also form starch and other carbohydrates, and there is nothing to prevent any surplus thus formed from becoming food for the animal. A remarkable case of symbiosis, involving a structural modification, is that of a carpenter bee (of the Oriental genus Koptorthosoma) and a certain mite. A special chamber, with a small orifice for entry, exists in the abdomen of the bee, in which the Acari are lodged. Here it is a little difficult to draw the

line between symbiosis and the parasitism, for instance, of the itch mite which burrows under the skin between the fingers.

SOCIAL SYMBIOSIS. Wheeler applies this term to the relations between ants and the various beetles, crickets, cockroaches, etc., which live at their expense. Of those beetles (Claviger, Paussus, etc.) that live in ant and termite nests certain ones seem to be tolerated or ignored by the ants. So completely agreeable to the ants is the presence of certain of the Staphylinidæ that the ants regurgitate food which they give to the beetles, and the beetles in the same manner share their supply with hungry ants. The ants feed the larval beetles with as much care as they do their own larvæ. They even clean the young beetles by licking them. See ANT; BEE; COMMENSALISM; EPIPHYTE; INSECT; LICHEN; MUTUALISM; PARASITE; ROVE-BEETLE; TERMITE.

Consult: O. Hertwig, *Die Symbiosis* (Jena, 1883); Geddes, *Nature*, vol. XXV. (1882); Brandt, *Archiv für Anatomie und Physiologie* (1882), and *Mittheilungen der zoologischen Station, Naples*, iv. (1883); Lankester, *Nature*, vol. XXVII. (1882). For symbiosis in insects, see the papers of Forel, Wasmann, Wheeler, etc.

SYMBOLISM (from *symbol*, from Lat. *symbolus*, *symbolum*, from Gk. *σύμβολος*, *σύμβολον*, mark, token, signal, sign, confession of faith, from *συμβάλλειν*, *symballein*, to compare, put together, from *σύν*, *syn*, together + *βάλλειν*, *ballein*, to throw). In its broadest sense, the representation of one thing by another, as of a sound by a letter, of a word or a concrete idea by a hieroglyph. Symbolism is most important in the history of art, especially of Christian art. Obviously no doctrine of religion can take form in outward act without some kind of symbolism; and accordingly every detail of the ancient Roman Catholic or Eastern rites is so planned as to suggest to the worshiper one or another aspect of abstract truth. In the plan and construction of the older churches the same idea is carried out as in their cruciform shape. Early Christian art represented Jesus under numerous symbols, among the commonest being the lamb, the fish, and the Greek letters Alpha and Omega (the beginning and the end). Similarly, the Holy Ghost was represented by a dove; and the olive branch denoted peace; the palm, triumph; and the anchor, faith or hope. In later art each one of the saints depicted may be recognized by some appropriate symbol, e.g. Saint Andrew by a cross in the shape of an X, or Saint Dominic by the lily and the star above his forehead. Consult: Clement, *Handbook of Legendary and Mythological Art* (2d ed., Boston, 1881); Knight, *The Symbolic Language of Ancient Art and Mythology* (2d ed., New York, 1876). See DÉCADENTS.

SYMBOLISTS. The name of a class of writers which sprang up after 1880 notably in France and in connection with verse. The symbolists regard symbolism as the expression of an idea by the introduction of a being or an object merely for the purposes of such expression. The characteristic means are the allegory, transposition, and allusion. The symbolists were in effect reactionists against realism. They concern themselves with general truths in contrast with actualities. They court erudition, adore the metaphysical and mysterious, and especially exalt the magic power and charm of music. Identified with the influence of Wagner, they seek music in language and accordingly the sonorousness of words; they suggest but do not name. Dreams, visions, and mythological tales are their proper subjects, and lyricism their favorite form of poetic expression. In their aim to unify and blend the arts and the functions of the senses, the extremists among them, like Arthur Rimbaud, associated the vowels with colors, etc. The metrical reforms of the French Symbolists have resulted in making French verse more free and large in its possibilities of effect, more subtle, intimate, and musical. The Symbolists, despite the vagaries which attend all new schools of literature and art, have left a permanent and desirable mark. Their general influence has been for the exclusive, the refined, the delicate, and the mystic beauties of the supranatural. Their verse has represented idealism, religious sentiment, a return to the ancient, and an inherent preference for solemn or fatalistic themes. Verlaine, Mallarmé, and Maeterlinck are the most noteworthy of the French and Belgian Symbolists. Among Symbolist plays those of De Curel may be noted. Symbolism reaches also into the domain of contemporary painting. For a statement of certain particular phases or developments of Symbolism, see DÉCADENTS.

SYMBOLS, MATHEMATICAL. The various signs and abbreviations used to facilitate mathematical expression. They are of the following kinds:

Of value.
  Hindu and other numerals. See NUMERALS.
Of operation.
  Addition, $+$, Σ.
  Subtraction, $-$.
  Multiplication, as in $a \times b$, $a \cdot b$, $(a + b)$, $\lfloor\underline{a}$ or $a!$
  Division, as in $a \div b$, $a:b$, a/b, x^{-n} $\left(=\frac{1}{x^n}\right)$.
  % (as in $6\% = \frac{6}{100}$).
  Involution, as in x^n.
  Evolution, as in $x^{\frac{1}{n}}$ or $\sqrt[n]{x}$.
  Differentation, d, δ, D.
  Integration, $\int$.
Of function.
  $f(x)$, $F(x)$, for f — function of x, F — function of x; ϕ $(x, y, \ldots)$, for phi-function of x, y, ...
Of quality.
  Positive number, $+a$.
  Negative number, $-a$.
  Absolute value, $|a|$.
  Imaginary, ai for $a\sqrt{-1}$.
Decimal, as in 3.2.
Of relation.
  Equality, $=$, ::.
  Indentity, $\equiv$.
  Inequality, as in $a < b$ (a less than b), $a > b$ (a greater than b), $a \not< b$ (a not less than b), $a \not> b$ (a not greater than b), $a \neq b$ (a not equal to b).
Of continuation.
  ....., as in a, a^2, a^3, ...

Of deduction.
∵ (since).
∴ (therefore).
Of aggregation.
( ), [ ], { }, ——
Of denominate numbers, as in $10, 3° 4′ 15″ (degrees, minutes, seconds), £20 3s. 2d. (pounds, shillings, pence), cwt. (100 lbs.), and various abbreviations.
Of geometry.
∠, ∠s (angle, angles).
⊥ (perpendicular to).
∥ (parallel to).
≅ (congruent to).
∼ (similar to).
= (approaches as a limit).
△, △s (triangle, triangles).
⊙, ⊙s (circle, circles).
□, □s (square, squares).
▭, ▭s (rectangle, rectangles).
▱, ▱s (parallelogram, parallelograms).
⌒ (arc).
a (radians).

The question of the origin and development of mathematical symbols is a large one, and science has not yet given satisfactory answers at many points. The probable origin of the remarkable digits 1 . . 9, is discussed in the article on NUMERALS. The origin of zero is unknown, there being no authentic record of its history before A.D. 400. The extension of the position system below unity is attributed to Stevin (1585), who called tenths, hundredths, thousandths, . . . *primes, sekondes, terzes,* and wrote subscripts to denote the orders, thus 4.628 was written $4_{(0)}\ 6_{(1)}\ 2_{(2)}\ 8_{(3)}$. But Rudolff (1525) and Kepler (1571-1630) used the comma to set off the decimal orders, and Bürgi (1552-1632) and Pitiscus (1612) in their tables used the decimal fraction in the form 0.32, 3.2. Although the early Egyptians had symbols for addition and equality, and the Greeks, Hindus, and Arabs symbols for equality and for the unknown quantity, from earliest times mathematical processes were cumbersome for lack of proper symbols of operation. The expressions for such processes were either written out in full or denoted by word abbreviations. The later Greeks, the Hindus, and Jordanus indicated addition by juxtaposition; the Italians usually denoted it by the letter P or p with a line drawn through it to distinguish it as an operation, but their symbols were not uniform. Pacioli, for example, sometimes used p and sometimes e, and Tartaglia commonly expressed the operation by φ. The German and English algebraists introduced the sign +, but spoke of it as *signum additorum* and first employed it only to indicate excess. Subtraction was indicated by Diophantus by the symbol ↓. The Hindus used a dot, while the Italian algebraists denoted it by M or m with a line drawn through the letter. The symbols $\bar{m}$ and *de* were, however, used by Pacioli. The German and English algebraists were the first to use the present symbol and described it as *signum subtractorum.* The symbols + and − appeared first in print in an arithmetic of Widmann (1489). The symbol × for 'times' is due to Oughtred (1631). To Rahn (1659) is due the present sign ÷ for division; Harriot (1631) used a period to indicate multiplication, and Descartes (1637) used juxtaposition. Leibnitz in 1688 employed the sign ∽ to denote multiplication and ∽ to denote division. Division among the Arabs was designated variously by $a - b$, a/b, $\frac{a}{b}$, but Clairaut (1760) made familiar the form $a : b$. Descartes made popular the notation a^n for involution and Wallis defined the negative exponent. The symbol of equality, =, is due to Recorde (1557), and the symbols >, <, for greater than and less than, originated with Harriot (1631). Viète (1591) and Girard (1629) introduced various symbols of aggregation. The symbol ∞ for infinity was first employed by Wallis in 1655. The symbols of differentiation dx and of integration $\int$ as used in calculus, are due to Leibnitz, as is also the symbol ∽ for similarity, as used in geometry. The symbolism ϕ, f, F, as used in theory of functions, is due to Abel.

Consult Cantor, *Vorlesungen über Geschichte der Mathematik* (2d ed., Leipzig, 1900).

SYME, sīm, JAMES (1799-1870). A noted Scotch surgeon, born in Fife, and educated at the University of Edinburgh. He was lecturer (1823-32) and professor (1833-48) of surgery at his alma mater, after having served as demonstrator under Liston. He was the inventor of the mackintosh waterproof cloth. He was clinical professor from 1829 to 1833 in Minto House Hospital, which he founded at his own expense. He was one of the ablest teachers and operative surgeons of the age. He devised resection of the joints, Syme's amputation of the foot, and excision of the lower jaw. He was the author of many valuable works, including *The Excision of Diseased Joints* (1831); *Principles of Surgery* (1832); the same, to which is added *Diseases of the Rectum* (1866); *Pathology and Practice of Surgery* (1848); *Stricture of the Urethra and Fistula in Perineo* (1849). Consult Paterson, *Memoir* (Edinburgh, 1874).

SYMINGTON, sīm'ĭng-tŏn, WILLIAM (1763-1831). A British inventor, born at Leadhills. In 1786 he constructed a working model of a steam road-carriage, and afterwards patented a steam-engine in which he obtained rotary motion by chains and ratchet wheels. In 1788 he and Patrick Miller used an engine constructed on the lines of this patent to propel a small pleasure boat on Dalswinton Loch. In the following year they experimented on a larger scale on the Forth and Clyde Canal and succeeded in attaining a speed of seven miles an hour. As the type of engine used was imperfect, however, Symington in 1801 patented another in which a piston rod guided by rollers was connected by a rod to a crank attached to the paddle-wheel shaft. In the following year he fitted out a boat called the *Charlotte Dundas,* which proved able to tow two barges a distance of 19½ miles in six hours. The Duke of Bridgewater, Symington's patron, was so well pleased with the boat that he ordered eight others to be constructed. Unfortunately for the inventor, however, the Duke died shortly afterwards, the order was canceled, and Symington was unable to find another patron.

SYMMACHUS, sĭm'mȧ-kŭs. Pope, 498-514. He was born in Sardinia, and was chosen to fill the vacancy left by the death of Anastasius II. A minority, however, of the Byzantine faction, set up as a rival the archipresbyter Laurentius. As a result of the schism, bloody encounters took

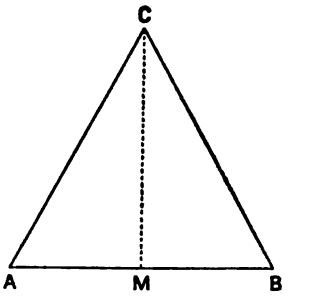
place, and the Ostrogothic King Theodoric, although an Arian, was appealed to, and gave his voice for Symmachus. Theodoric, being again appealed to, caused the Bishop of Altinum to administer the affairs of the Church for a time, and left the decision to a synod. In its fourth session the synod (502) finally decided in favor of Symmachus. In vindication of the action of the synod the deacon Ennodius, afterwards Bishop of Ticinium (Pavia), gave clear expression to the principle that the Pope (Ennodius is among the first to limit this title to the Bishop of Rome) is above every human tribunal and is responsible only to God himself. Later councils during Symmachus's pontificate condemned all interference of laymen in the election of popes and regulated the disposition of goods belonging to the Church.

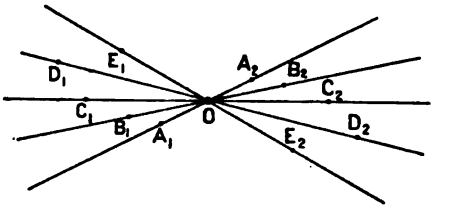
SYMMACHUS, GREEK VERSION OF. See BIBLE, section on *Versions*.

SYMMACHUS, QUINTUS AURELIUS. A distinguished Roman orator, scholar, and statesman, who was born probably not long after A.D. 340, was educated in Gaul, and after holding several lesser offices, became prefect of Rome (A.D. 384). Seven years later he was raised to the consulship. The date of his death is unknown, but we know that he was alive in A.D. 404. A sincere pagan in an age when classic paganism was almost extinct, he proved in his own person a pattern of its choicest virtues, and manfully, if in vain, strove to regain for it a place of honor in the State. Symmachus's extant writings consist of ten books of letters (*Epistolarum Libri X.*) and the fragments of nine orations. The best editions of Symmachus's entire works are by Seeck (Berlin, 1883) and Kroll (Leipzig, 1893). Consult: Morin, *Etude sur la vie et les écrits de Symmaque, préfet de Rome* (Paris, 1847); Dill, *Roman Society in the Last Century of the Western Empire* (London, 1899).

SYMMES, simz, JOHN CLEVES (c.1780-1829). An American soldier and author, born in Sussex County, N. J. He entered the United States Army as ensign in 1802, became captain January 20, 1813, and served through the War of 1812, distinguishing himself particularly at Niagara and in the sortie from Fort Erie. He subsequently lived in Newport, Ky., and gave his entire time to developing and advocating his theory that the earth and all the other planetary bodies are composed of a number of hollow concentric spheres, open at their poles. He believed the inside of the earth to be habitable, and in 1822 and again in 1823 petitioned Congress to fit out an expedition to test the theory. In support of his contention he published many pamphlets and a volume entitled *Theory of Concentric Spheres* (1826). Consult an article on "Symmes's Theory of the Earth," in the *Atlantic Monthly* for April, 1873.

SYMMETRY (Lat. *symmetria*, from Gk. *συμμετρία*, from *σύμμετρος*, *symmetros*, having a common measure, from *σύν*, *syn*, together + *μέτρον*, *metron*, measure, from *μετρεῖν*, *metrein*, to measure). A term used in geometry to express a characteristic property of two congruent or quasi-congruent figures which have a certain relation with respect to a point, line, or plane. Two systems of points, A_1, B_1, C_1, ..., A_2, B_2, C_2, ..., are said to be symmetric with respect to an axis when all lines $A_1 A_2$, $B_1 B_2$, ... are bisected at right angles by that axis. Two figures are said to be symmetric with respect to an axis when their systems of points are symmetric with respect to that axis. A figure is





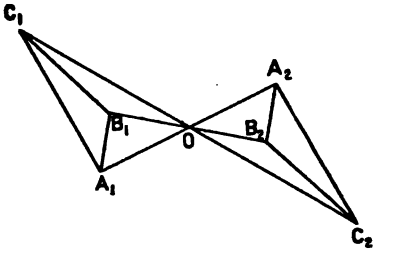


FIGURE SYMMETRIC WITH RESPECT TO AN AXIS.

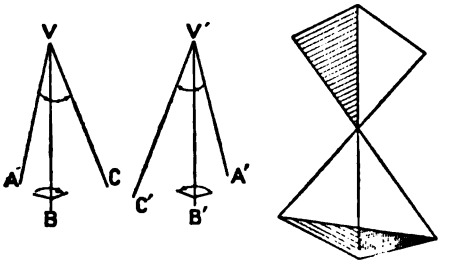
said to be symmetric with respect to an axis when the axis divides it into two symmetric figures. Two systems of points A_1, B_1, C_1, ..., and A_2, B_2, C_2, ..., are said to be *symmetric with respect to a centre O* when all lines $A_1 A_2$, $B_1 B_2$, $C_1 C_2$, ..., are bisected by O.

POINTS SYMMETRIC WITH RESPECT TO A CENTRE.



SYMMETRICAL TRIANGLES.

Two figures are said to be symmetric with respect to a centre when their systems of points are symmetric with respect to that centre. E.g. in the figure triangles $A_1 B_1 C_1$, $A_2 B_2 C_2$ are symmetric with respect to O.

Figures of three dimensions besides being symmetric with respect to an axis or a centre may be symmetric with respect to a plane. E.g. the sphere is symmetric with respect to its centre, with respect to any diameter as axis, and with respect to any diametrical plane as a plane of symmetry. Symmetric polyhedral angles may be considered as quasi-congruent, and are such as have their dihedral angles equal, and the plane angles of their faces also equal, but arranged in reverse order.

Thus, in the following figure, V and V′ are symmetric trihedral angles, the letters showing the reverse arrangement. Opposite polyhedral angles are such that each is formed by producing the edges and faces of the other through the vertex,

and are symmetric. The theory of symmetric figures is closely related to that of similarity (q.v.).

SYMMETRIC POLYHEDRAL ANGLES. OPPOSITE POLYHEDRAL ANGLES.

In algebra, an algebraic function is said to be *symmetric* with respect to certain letters when these letters can be interchanged without changing the form of the expression. E.g. $x^2 + 2xy + y^2$ is symmetric as to x and y, because if x and y are interchanged it becomes $y^2 + 2yx + x^2$, which is the same as the original expression.

A knowledge of symmetry and homogeneity (q.v.) is of great value in factoring. E.g. to factor $f(x,y,z) = x(y^2-z^2) + y(z^2-x^2) + z(x^2-y^2)$. The expression vanishes for $x = y$, hence $x-y$ is a factor by the remainder theorem (q.v.). But $f(x,y,z)$ is symmetric with respect to x,y,z, therefore $y-z$, $z-x$, are also factors. And $f(x, y, z)$ being homogeneous of the fourth degree, it must contain another factor of the first degree; but such a homogeneous symmetric factor can be $x+y+z$ only. Whence the literal factors are $x-y$, $y-z$, $z-x$, $x+y+z$. On algebraic symmetry consult Beman and Smith, *Elements of Algebra* (Boston, 1900).

SYMMETRY. The general tendency in animals toward a symmetrical arrangement of parts. Thus man is bilaterally symmetrical, i.e. the external parts or limbs are arranged in pairs on each side of his body. So with the annelid worms, the lobster, centipede, and scorpion. On the other hand, this symmetry is wanting in some of the internal organs—those which are single. Haeckel has elaborated a scheme of fundamental forms of which the following is a summary.

(1) *Anaxial or symmetrical* forms, with no fixed central point or definite axis (many Protozoa and most sponges).

(2) *Homaxial or spherical* animals have the fundamental shape of a sphere, the parts of the body being arranged concentrically around a fixed central point (a few spherical Protozoa, chiefly Radiolaria).

(3) *Monaxial or Radial Symmetry.* In polyps, owing to their becoming fixed in larval life, the digestive canal opens upward, the parts being arranged around the single or main axis, radiating from it. In cross-section the radial symmetry is seen to be very marked. The parts are like reëntering wedges and were called by Agassiz spheromeres (cœlenterates and echinoderms).

(4) *Bilateral Symmetry.* Here the parts are symmetrically arranged on each side of the main or sagittal axis (annelid worms, arthropods, vertebrates).

INTERNAL AND EXTERNAL SEGMENTATION. This is due to the division of the body into segments, indicated externally by infoldings of the integument (annelids, tapeworms, arthropods). The external signs of segmentation may be effaced or wanting. Thus in man the body is segmented only internally; in the lancelet the muscles are arranged segmentally and can be seen on the outside of the body. In the annelid worms (earthworm, etc.) not only is the body segmented externally, bearing setæ or parapodia on each segment, but the nerve-ganglia, nephridia or segmental organs, the vascular arches or transverse arteries, and the septa of the body, i.e. the partitions between the segments, are repeated metamerically.

HOMONOMOUS AND HETEROMEROUS SEGMENTATION. The earthworm, the galley-worm (Julus), and the centipedes afford examples where the trunk-segments are for the most part alike in size and appearance, and bear similar locomotive setæ or jointed appendages. In most crustacea and insects, as well as in the higher vertebrates, 'heteronomy' prevails. Homonomy is characteristic of the more primitive forms, heteronomy of later more specialized types. Thus the transfer of parts headwards in crabs (cephalization), due to the excessive development of certain of the head segments and the atrophy of those behind, brings about a decided irregularity in the size and shape of the segments. Heteronomy is thus accompanied by a division of physiological labor due to the specialization of the segments and their appendages. It is owing to the hypertrophy of certain segments and partial or total reduction and even in some cases loss of segments or portions of segments, with their appendages, that the varied forms of arthropods are produced. Consult Haeckel, *Generelle Morphologie* (Berlin, 1866).

SYMONDS, sīm'ondz *or* sī'mondz, JOHN ADDINGTON (1840-93). An English critic and literary historian, born at Bristol. From Harrow he passed to Balliol College, Oxford, where he graduated with distinction, winning the Newdigate prize, with a poem on *The Escorial* (1860), and a fellowship at Magdalen College (1862). He began the study of law, which ill health compelled him to abandon. He settled at Clifton and began literary work in earnest. Subsequently he passed much time on the Continent, and for several years lived at Davos, in Switzerland. *Our Life in the Swiss Highlands* (1891) tells charmingly of his mountain home. He died in Rome. Symonds's reputation rests mainly on *The History of the Italian Renaissance* (7 vols., 1875-86), and the excellent translations of the *Vita di Benvenuto Cellini* (1887) and the *Sonnets of Michelangelo and Campanella* (1878). Other striking books are the *Introduction to the Study of Dante* (1872), *Essays, Speculative and Suggestive* (1890), *In the Key of Blue* (1893), and *Walt Whitman* (1893). Symonds also contributed to the "English Men of Letters" good lives of Shelley (1878) and of Sir Philip Sidney (1886). Besides all these and much other miscellaneous work, he composed a considerable body of verse, admirable in technique, but wanting in inspiration. This includes *Many Moods* (1878); *New and Old* (1880); *Animi Figura* (1882); and *Vagabunduli Libellus* (1884). Both his verse and his prose show the thorough interpenetration of his

nature by the culture and the ideals of the Renaissance period with which he was so familiar. He was celebrated as a fascinating conversationalist; Stevenson, who passed some time at Davos with him, has commemorated him in the essay on "Talk and Talkers" in *Memories and Portraits*, under the name of Opalstein. Consult also the biography by Brown (London, 1895).

SYMONS, sĭm'onz, ARTHUR (1865—). An English essayist and verse writer, born in Wales. He attended several private schools and traveled in France and in Italy. He has written for the *Athenæum* and the *Saturday Review*, and was editor of the short-lived *Savoy* (1896). As a literary critic, Symons is seen at his best in *Studies in Two Literatures* (1897), dealing with contemporary English and French writers. These essays possess a charm and finish recalling Walter Pater. Symons has published *An Introduction to the Study of Browning* (1886) and *The Symbolist Movement in Literature* (1899). He has produced a body of graceful and tender verse in *Days and Nights* (1889); *Silhouettes* (1892); *London Nights* (1895); *Amoris Victima* (1897); and *Images of Good and Evil* (1900)—all showing a marked influence of the recent school of French Symbolists. Two volumes of poems (1902) contain, with some new verses, all he wished to preserve from earlier volumes.

SYMPATHY (Lat. *sympathia*, from Gk. *συμπάθεια*, *sympatheia*, fellow-feeling, sympathy, from *συμπαθής*, *sympathēs*, having like feeling, sympathetic, from *σύν*, *syn*, together + *πάθος*, *pathos*, feeling). In its broadest sense, the reproduction in one's self of a particular condition (physiological, psychophysical, or psychological) presented by other living creatures in one's perceptual or ideal environment. In genetic psychology, sympathy is a form of ejective or social consciousness, based ultimately upon a group of organic sensations (q.v.). The motor attitude assumed by gregarious animals in defense of their kind is different from the attitude adopted under the influence of personal fear. When consciousness becomes representative, and free ideas are formed (see IDEA), the sense-basis of the former attitude is associated with ideas of others' suffering and rescue, that of the latter with ideas of one's own danger, safety, escape, etc. This is the stage of sympathetic consciousness proper. In general psychology, sympathy is one of the great emotional types, covering such different individual emotions as love, anger, contempt, aversion, chagrin, resentment, etc. (See EMOTION; ANGER.) For the ethical importance of sympathy, see ALTRUISM, and the references there given. See also ANTIPATHY.

SYMPETALÆ. One of the two great groups of dicotyledons (q.v.).

SYMPHONY (Lat. *symphonia*, from Gk. *συμφωνία*, unison of sound, harmony, from *σύμφωνος*, *symphōnos*, agreeing in sound, harmonious, from *σύν*, *syn*, together + *φωνή*, *phōnē*, sound, voice). In music, a word used in two different senses: (1) The instrumental introduction and termination of a vocal composition, sometimes called *ritornello;* (2) a composition for a full orchestra, consisting generally of four movements. The most usual though not unvarying order of movements is a brilliant allegro, ushered in by a slow introduction, an adagio or andante, a scherzo with its trio, and the finale, again an allegro. For the origin of the modern symphony we must go back to the beginnings of opera early in the seventeenth century, when the name *Sinfonia* was given to the short instrumental prelude which preceded the opera. The early history of the symphony is, therefore, that of the overture (q.v.). About the middle of the eighteenth century composers began to write separate *sinfonie* exclusively for concert performance. The three parts of the older overture, which had then only a loose connection, were entirely detached and became separate movements. Haydn introduced a fourth movement, the minuet (q.v.), which he inserted before the finale. He also adopted for the first movement the sonata form (q.v.). By individualizing the separate instruments and grouping them in families Haydn also established the symphony orchestra and thus made the symphony what it is to-day. Beethoven extended the form considerably, particularly the development section of the first movement, and also replaced the minuet by the more elaborate scherzo (q.v.). Beethoven also increased the orchestra considerably. (See ORCHESTRA.)

SYMPLEGADES, sĭm-plĕg'ă-dēz (Lat., from Gk. *Συμπληγάδες*, that strike together, from *συμπλήσσειν*, *symplēssein*, to strike together, from *σύν*, *syn*, together + *πλήσσειν*, *plēssein*, to strike). Two mythical floating islands in the Pontus Euxinus, which dashed against each other until they became fixed when the Argo made its way between them. See ARGONAUTS.

SYMPOSIUM (Lat., from Gk. *Συμπόσιον*, banquet). (1) A philosophical treatise by Xenophon, discussing the nature of love and friendship, and depicting the character of Socrates, who is one of the speakers. The meeting place is the house of the Athenian Callias. The work conveys a good idea of the conduct of an Athenian drinking party. (2) A dialogue by Plato, intended probably as a corrective of the similar work of Xenophon. Its subject is the nature of love. Its scene is the house of the poet Agathon, and Socrates and Alcibiades are among the speakers.

SYMPTOM (from Gk. *σύμπτωμα*, *symptōma*, chance, mischance, symptom, from *συμπίπτειν* *sympiptein*, to fall in with, happen, coincide, from *σύν*, *syn*, together + *πίπτειν*, *piptein*, to fall). A medical term denoting a phenomenon by which a physician judges of the presence of disease. A group, or syndrome, of symptoms enables the physician to judge directly of the nature of and to identify the disease, or to decide upon the lesions or morbid tissue changes, and then determine what disease is present. This decision is called a diagnosis. (See PATHOLOGY.) Symptoms are *objective*, including those perceived by the physician and found upon examination, such as heart murmurs, rise of temperature, etc.; or *subjective*, including those perceived only by the patient, as pain, ringing in the ears, etc. Symptoms are termed *pathognomonic* when they are sure signs of a certain disease; e.g. the syndrome of occipital headache, severe pain in the orbits, acute nasal catarrh, rheumatoid pains in joints and muscles, and great prostration is almost always pathognomonic of the grippe.

SYNAGOGUE (Gk. *συναγωγή, synagōgē*, assembly, collection, from *συνάγειν, synagein*, to bring together, from *σύν, syn*, together + *ἄγειν, agein*, to lead; translation of Heb. *bēth-hakkeneseth*, the house of assembly). The name applied to the place of assembly used by Jewish communities primarily for public worship. The origin of this institution is probably to be traced to the period of the Babylonian captivity, when religious needs in the absence of an official cult could only be satisfied by private assemblies for religious communion. The example set during the Babylonian Exile led to the establishment of synagogues in Palestine after the days of Ezra, and with the impetus then given to the study of the law a further factor was introduced which encouraged the institution of assembly-houses for prayer and study. Although express notices of the synagogues are not found in the literature till the last century B.C., all indications point to their existence in the towns and even villages of Palestine at the time of the Maccabees.

Synagogues were erected from the common funds or free gifts of the community and supported by taxes and donations. Regarding their architecture it would appear that in Palestine the Græco-Roman model of public buildings was followed, though with some essential modifications. Abundant ornamentation was a feature both of the exterior and interior. The larger synagogues were divided by rows of pillars into several aisles and some had porticoes in front. In later times in Europe the Romanesque style was adopted, and in more modern times Moorish architecture is frequently chosen as a model. Little is known of any special law respecting the construction of these buildings, save that the faces of the worshipers should be directed toward Jerusalem; that, in accordance with the verse in the Psalms, there should be a slight descent of a step or two on entering the edifice; that the building should stand, if feasible, on a slightly elevated ground, or be somehow or other made visible from afar. Within at the extreme eastern end was the holy ark, or chest (*tēbāh*) containing several copies of the Pentateuch, from which the periodical readings were chanted. In front of this was the stand of the public reader of the prayers, not far from which was suspended the everlasting lamp. On a raised platform in the middle of the synagogue was the place of the reader or preacher. The women, who were not counted as members of the congregation, sat separated from the men.

The affairs of the synagogue were administered by a board of 'ancients' or 'elders,' at whose head stood a chief or principal (*Rōsh hakkeneseth, archisynagogos*). The 'chief' was not a scribe, though taking rank immediately after the scribes. The officiating minister, whose office it was to recite the prayers aloud, was called *shĕliaḥṣibbūr*, messenger of the community. The *chazzān* had general charge of the sacred place and its books and implements. He had to present the scroll to the reader, received it back after the reading was finished, rolled up the scroll and deposited it in the chest, and it was he who announced the advent of the Sabbath or of a holy day from the roof of the synagogue with a thrice repeated trumpet-blast. During the week-days he had to teach the children of the town or village. He had to be initiated by a solemn imposition of hands. The name of *chazzān*, however, at a later period, came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons, who collected or distributed the alms, possibly the same as the *baṭlanim* or 'idle men,' whose office in relation to the synagogue cannot be exactly determined now, but who had always to be ready for the purpose of making up the requisite number of ten worshipers, were further attached to the general body of officials. The third, sixth, and ninth hours of the day were the times appointed for daily worship; the more special days were Monday and Thursday, when the judges sat, and the villagers came to town, and Saturday, on which the forms of some of the prayers were altered according to the occasion.

The reading from the Scriptures, though in Hebrew, was coupled in the synagogues of Palestine and Babylonia with a translation or paraphrase in the current Aramaic idiom, and presumably in the synagogues of Egypt a Greek translation was employed, but the chief prayers were always pronounced in Hebrew, though the Talmud admits the use of other languages in worship. Besides the prayers and the readings, a feature of early synagogue worship was the exposition of the law or of the lesson of the day by a competent person. In course of time a more elaborate liturgy developed. The oldest complete ritual, known as *siddur* ('arrangement'), dates from the year A.D. 880, and was compiled by a Rabbi Amram. In the liturgy as finally evolved two distinct elements are discernible: the *Shema'* ('Hear, O Israel,' etc.), being a collection of the three passages, Deuteronomy vi. 4-9, xi. 13-21, and Numbers xv. 37-41, expressive of the unity of God and of His government over Israel, put together without any extraneous addition; and the *Tĕphillāh* or prayer, consisting of a certain number of supplications, with a hymnal introduction and conclusion, followed by the priestly blessing. The single portions of this prayer gradually increased to eighteen and the prayer itself received the name of *Shĕmōnāh 'eshĕh* (eighteen). For a long time the prayers were recited only by the reader, the people joining in silent responses and amens. These readers by degrees—chiefly from the tenth century—introduced occasional prayers of their own, and ultimately religious doctrine, history, saga, angelology, and mysticism, interspersed with biblical verses, are found put together in a mosaic of the most original and fantastic, often grand and brilliant, often obscure and feeble kind. The ritual differed in different countries. At the beginning of the nineteenth century a movement began in Germany for the reform of the ritual and gradually spread to other countries. At first the changes consisted in the shortening of certain prayers, the omission of others and the introduction of German, English, or French by the side of the Hebrew.

The synagogues contributed more than anything else to the steadfast adherence of the people to their religion and liberty as long as there was any possibility of keeping both intact. At the same time they gradually undermined the priestly and aristocratic element that gathered around the temple, its gorgeous worship and kingly revenues. Their importance as a place of

instruction as well as a place of worship was of profound influence on the development of Judaism. Both primary and advanced instruction in the Scriptures and subsequently in Talmudic literature was given in the synagogue, and in the early centuries of the Christian Era legal decisions were likewise announced there. The synagogue could also be used as the place of mourning for prominent members of the community, and there are instances on record of the use of synagogues for political gatherings. In Babylonia travelers were accommodated in the synagogue and ate their Sabbath meals there. In view of these various uses to which the synagogue was put, it is not surprising that it became in the Middle Ages the centre of the religious and intellectual life of the Jews and in a measure of their social life as well. The 'reform' movement within Judaism as well as the extension of the intellectual interests of the Jews has resulted in narrowing the influence and scope of the synagogue to purely religious affairs, though in orthodox Jewish communities in Eastern Europe and in the Orient the former status of the synagogue is still in large measure maintained.

SYNAGOGUE, THE GREAT (Heb. *hakkeneseth haggĕdōlāh*). An alleged assembly or synod, said to have been founded and presided over by Ezra and to have controlled the national and religious fortunes of the Jews after the return from Babylon, c.450-200 B.C. Its membership is generally given as 120, but sometimes as 80. The palpable chronological discrepancies that occur in the early accounts about this synod, together with other doubtful points, have led modern scholars to deny its existence. It is not mentioned by Josephus or the Apocrypha and is only twice referred to in the Mishna (*Pirke Aboth* I., 1 and 2). Even according to the Talmudical notices the 'great synagogue' continued only for a single generation. According to these notices the men of the great synagogue secured the acceptance of certain books of the Old Testament (Proverbs, Canticles, Ecclesiastes); they promoted the work of copying the Torah, devoted themselves to the perfection of a daily ritual, and introduced certain changes into the Old Testament text in order to avoid misunderstandings. The notion that they collected the books of the Old Testament and fixed the canon had no authority in the Talmud, and indeed does not arise till the sixteenth century. Kuenen has traced the origin of the name to the 'great assembly' which is described in Nehemiah viii.-x. This assembly was of a popular character, and no doubt marked an epoch in the history of post-exilic Judaism. An uncritical age made of this 'assembly' a permanent institution and attributed to it the various steps taken in the natural unfolding of that phase of Rabbinical Judaism which came to a temporary close when the canon of the Old Testament was definitely established. While some scholars (notably D. Hoffmann of Berlin) still cling to the traditional view, Kuenen's results have been accepted by the great majority. Consult his essay in *Gesammelte Abhandlungen*, pp. 125-160 (Freiburg, 1894); Hoffmann's reply will be found in the *Magazin für die Wissenschaft des Judenthums*, vol. x. (1883), pp. 45-63. See also L. Krauss, "The Great Synod," in the *Jewish Quarterly Review*, vol. x. (1898), pp. 347-377.

SYNCHRONOUS MOTORS. See DYNAMO-ELECTRIC MACHINERY.

SYNCLINE (from Gk. *συνκλινειν*, *synklinein*, to lean together, from *σύν*, *syn*, together + *κλινειν*, *klinein*, to lean). A term used in geology for the structure formed by the bending of strata into a basin of downward fold, the limbs of the fold dipping toward each other and meeting at a line called the synclinal axis. Where the strata dip downward from all sides a peculiar type of syncline arises, known as a geologic basin; in this case the synclinal axis is reduced to a point. The syncline, structurally, is the complement of the anticline (q.v.). See GEOLOGY.

SYNCOPATION (from Lat. *syncopatus*, p.p. of *syncopare*, to syncopate, from *syncope*, from Gk. *συγκοπή*, *synkopē*, a cutting short, from *συγκόπτειν*, *synkoptein*, to abridge, from *σύν*, *syn*, together + *κόπτειν*, *koptein*, to cut). In music, the joining together of two similar notes by means of a tie, so that the accent intended to fall on the second (strong beat) comes on the first (weak beat). The effect produced is that of contra-tempo. The following example is from Beethoven's overture "Lenora No. 3:"

The effect of syncopation can also be produc by merely shifting the accent by means of marks (*Eroica Symphony*, Scherzo):

The North American Indians made extensive use of syncopation, and in this were followed by the Southern negroes. In fact, the music of nearly every savage or semi-civilized nation shows traces of syncopated rhythm.

SYNCOPE. See FAINTING.

SYNCRETISM (from Gk. *συγκρητισμός*, *synkrētismos*, combination against a common enemy, from *συγκρητίζειν*, *synkrētizein*, to combine against a common enemy, apparently from *σύν*, *syn*, together + *κρητίζειν*, *krētizein*, to act like a Cretan, from *Κρής*, *Krēs*, Cretan). A term used: (1) in ancient times, politically, to designate the Cretan custom of disregarding all internal dissensions whenever a controversy with a for-

eign country occurred; (2) in the sixteenth century, philosophically, to denote the efforts made to reconcile opposing systems; (3) in the seventeenth century, theologically, first by Pereus in his *Irenicon*, and afterwards to describe the views of Calixtus and his followers, who sought to heal the schism in the Church by making the traditions of the first five centuries of equal authority with the Bible, and by adopting the Apostles' Creed as the common basis of all Christian denominations and a sufficient definition of true Christianity.

SYNDIC (from Lat. *syndicus*, from Gk. *σύνδικος*, *syndikos*, advocate, public officer, from *σύν*, *syn*, together + *δίκη*, *dikē*, justice, law, right). A name which has at different times and in different countries been given to various municipal and other officers. In Geneva the chief magistrate was formerly called the syndic. The syndics of cities in France, under the old régime, were officers delegated by the municipality as agents or mandatories; the various trading companies in Paris and the university had also their syndics; and in the University of Cambridge the same name is applied to members of special committees of members of the senate appointed by grace from time to time for specific duties. In Italy the mayors of towns are called syndics.

SYNERGISM (from Gk. *συνεργία*, *synergia*, coöperation, from *συνεργός*, *synergos*, coöperative, from *σύν*, *syn*, together + *ἔργον*, *ergon*, work). The name given to a doctrine of theology which teaches that in the work of conversion the will of man is not wholly passive, but can coöperate, through consent, with the Divine Spirit. In the time of the Reformation Melanchthon and his school were inclined to this view, while the strict Lutherans opposed it and charged its advocates with favoring Pelagianism (q.v.). In 1557 and later the question was hotly discussed, Pfeffinger and Strigel taking the lead on the Synergistic side, Flacius and Amsdorf (qq.v.) on the opposite. The Wittenberg divines in general favored the doctrine, the Mansfield divines opposed it. Finally it was condemned in 1580 in the third article of the Formula of Concord. See CONCORD, BOOK OF.

SYNE'SIUS (Lat., from Gk. *Συνέσιος*) (370-?). A Neo-Platonic philosopher and Christian bishop. He studied philosophy in Alexandria, under Hypatia, to whom he was ever warmly devoted, and his life well illustrates the combination of Neo-Platonism and Christianity so characteristic of the fourth century. For three years (397-400) he served as envoy at the court of Arcadius, in Constantinople, where he won popularity and influence. His famous speech *On Kingship* was delivered in the Emperor's presence, and was a bold discussion of the duties and frailties of monarchs. Synesius was made Bishop of Ptolemais in 410, against his own desire, and with the apparent stipulation that he should not be obliged to give up his wife or his philosophy. He administered his see with conscientious fidelity, notwithstanding the fact that his personal tastes were far from ecclesiastical. Neither the time nor the place of his death is known. Synesius's writings include about 150 letters; *Egyptian Tales, or on Providence*, a sort of historical allegory defending the idea of a providential government of the world; a defense of the philosophic life, entitled *Dio* (after Dio Chrysostom); a humorous work, called *Praise of Baldness*, suggested by Dio's *Praise of Hair;* and ten *Hymns*, which are partly pagan and partly Christian. His general theological point of view and his distinctive characteristics are well brought out in Charles Kingsley's novel, *Hypatia*, in which Synesius figures. For his works, consult: Migne, *Patrologia Græca*, lxvi. In general, consult: Glover, *Life and Letters in the Fourth Century* (Cambridge, 1901); Druon, *Etudes sur la vie et les œuvres de Synésius* (Paris, 1859); Volkmann, *Synesius von Cyrene* (Berlin, 1869).

SYNOD (Lat. *synodus*, from Gk. *σύνοδος*, assembly, meeting, coming together, from *σύν*, *syn*, together + *ὁδός*, *hodos*, way, road). A term applied almost exclusively to ecclesiastical assemblies convoked for the discussion and decision of ecclesiastical affairs. Synods or church councils are of five kinds: Ecumenical, general, national, provincial, and diocesan or local. By the law of the Roman Catholic Church the decrees of a national or provincial synod must be submitted to the Pope, and unless confirmed by him, or at least suffered to pass for two years without condemnation, are not held to be valid. The term synod has been preserved to describe courts in the Presbyterian system of church government which rank above the presbytery and the synod either is subordinate to a General Assembly or is itself the supreme court of the Church. The courts above the classes in the Dutch and German Reformed churches are called synods. In the organization of the Lutheran churches the synod is the highest representative body. Two of the Eastern churches have preserved the synod. The Holy Governing Synod of All the Russias is the highest ecclesiastical authority for the established Church of the Russian Empire. It consists of several metropolitans and other prelates and officials—the Chief Procurator of the synod representing the Czar. It was instituted by Peter the Great in 1721, to take over the jurisdiction formerly exercised by the Patriarch of Moscow. The orthodox national Church of the Kingdom of Greece is also governed by a synod of archbishops and bishops independent of the jurisdiction of any patriarch. For other conciliar organizations, see COUNCIL.

SYNODIC (Lat. *synodicus*, from Gk. *συνοδικός*, *synodikos*, relating to a conjunction, from *σύνοδος*, *synodos*, assembly, meeting, coming together). In astronomy, the epithet applied to the period of time which elapses between two successive conjunctions (q.v.) of a planet with the sun, as seen from the earth. In the case of the moon, the synodic period is therefore the time elapsing between two successive new moons. See MOON.

SYNONYM (Lat. *synonymum*, from Gk. *συνώνυμον*, *synōnymon*, neu. sg. of *συνώνυμος*, *synōnymos*, having the same name or meaning, from *σύν*, *syn*, together + *ὄνομα*, *onoma*, name). A word which nearly coincides in meaning with another, as clear, transparent; bright, limpid; fair, cloudless; serene, plain; lucid, perspicuous; patent, obvious; visible, evident. There is, however, in nearly every case a slight individual shade of meaning in each synonym. The development of synonyms is one first of convergence and then of divergence. That is, the meanings are originally quite distinct.

In the course of semasiological evolution, however (see SEMASIOLOGY), the particular words which tend to become synonymous overlap in meaning. This process may then continue till the words become identical in meaning. In this case the result is suppression of one of the terms, either complete, or, less usually, partial. The latter process gives the so-called suppletive or composite inflection, illustrated in such English verbs as *am, be, was*, or *go, went*, in which verb-roots originally distinct have coalesced. If, on the other hand, synonyms do not become identical, they tend to become so specialized in meaning with respect to each other that they not only retain for the most part their original distinctions, but frequently develop others. The main stylistic use of synonyms is to give variety and accuracy of diction. One of the criteria of excellence of a language is its synonyms, and herein English ranks as one of the foremost tongues. Consult, for English synonyms: Roget, *Thesaurus of English Words* (new ed., London, 1883); Soule, *Dictionary of English Synonyms* (new ed., Philadelphia, 1895); Crabbe, *English Synonyms* (new ed., New York, 1891); Smith, *Synonyms Discriminated* (4th ed., London, 1890).

SYNOVIAL MEMBRANE and **FLUID** (from Neo-Lat. *synovialis*, from *synovia*, lubricating fluid secreted by a synovial membrane, so called because it resembles the white of an egg, from Gk. *σύν, syn*, together + Lat. *ovum*, egg). In every joint in which a considerable range of motion is required, the osseous segments (or contiguous extremities of bones) are separated by a space, which is called the cavity of the joint. The end of each of the bones entering into the composition of the joint is incrusted by a layer of articular cartilage adapted to its form, and the entire cavity of the joint is lined by a delicate membrane, which is termed the *synovial membrane*, which secretes a peculiar viscid matter, termed *synovia*, or *synovial fluid*, for the purpose of lubricating the inner surface. Being a serous membrane, a synovial membrane is always a closed bag, like the pleura, for example, with an attached and a free surface, the latter being smooth and moist. The minute structure of a synovial membrane is much the same as that of serous membranes elsewhere. (See HISTOLOGY.) A very simple form of synovial membrane—anatomically known as a *bursa*—is employed to facilitate the gliding of a tendon of a muscle or of the integument over a projection of bone. It consists of a bag connected by areolar tissue with the neighboring parts, and secreting a fluid in its interior. These bags are sometimes prolonged into *synovial sheaths*, which surround long tendons, such as those of the flexor and extensor muscles of the fingers and toes. In felon (q.v.), when inflammation extends to one of the sheaths, and gives rise to the formation of adhesions, the motion of the inclosed tendon is destroyed, and a permanently stiff finger is the result. See SYNOVITIS.

The *synovial fluid*, or *synovia*, consists of water holding in solution mucin, albumen, fat, and inorganic salts. Excessive movement diminishes its amount, makes it more inspissated, and increases the mucin, but diminishes the salts.

SYNOVITIS (Neo-Lat., from *synovia*, lubricating fluid secreted by a synovial membrane). Inflammation of a synovial membrane. Although inflammatory processes involving joints frequently start in an inflammation of the synovial membrane, they rarely confine themselves to this membrane, but spread to and involve the surrounding tissues. It is for this reason that, especially in discussing the pathology of joints, the term synovitis, which properly means inflammation of the synovial membrane only, has been displaced by the term arthritis, which signifies inflammation of the joint in general, including the synovial membrane.

ACUTE ARTHRITIS is usually an exudative inflammation and may be serous, sero-fibrinous, or suppurative in character. In serous arthritis there is congestion of the synovial membrane with a serous exudate into the joint cavity. With the subsidence of the inflammation the serum may be absorbed and the joint return to its normal condition, or, becoming infected, may pass on to suppuration. The acuteness of the condition may pass off and the joint go on to a chronic inflammation. In sero-fibrinous arthritis there is in addition to the serum more or less fibrin in the joint cavity. Suppurative arthritis is an infectious condition due to the presence of bacteria. The exudate is purulent, while the synovial membrane is usually thickened, dull, and infiltrated with pus cells. Suppurative arthritis is apt to accompany or follow some one of the infectious diseases, as e.g. pyæmia, puerperal fever, pneumonia, gonorrhœa, diphtheria, and scarlet fever. Acute rheumatic arthritis or acute articular rheumatism is usually an exudative inflammation in which the exudate is serous in character and in which there is a successive involvement of different joints.

CHRONIC ARTHRITIS. The most important forms of chronic arthritis are simple chronic arthritis, arthritis deformans, rheumatic arthritis, gouty arthritis, and tubercular arthritis. In simple chronic arthritis there is a serous exudation into the joint cavity; the synovial membrane is thickened, pale, and rough. The exudate may be clear, thin, and watery, or may be cloudy and thick from the presence of minute particles of fibrin, or of lymphoid or endothelial cells. The amount of fluid is sometimes large and may result in rupture of the joint capsule or in so separating the joint surfaces that dislocations occur. In that peculiar form of chronic inflammation of the joints known as arthritis deformans there is a combination of destruction of parts of the joint with new bone formation which leads to extensive deformities. The joints most commonly involved are those of the fingers, hips, knees, and feet. In gouty arthritis there is a deposit of urates in and about the joints. These deposits take place in the cartilages and in the connective tissue and in the ligaments around the joints or even in the subcutaneous tissue. The deposit may be in the form of crystals or of whitish concretions. In tubercular arthritis the lesion is that of a tubercular inflammation modified by the nature of the tissues in which the inflammation occurs. The process may originate in the joint, but more frequently represents an extension to the joint of tubercular inflammation of the bones. Tubercular arthritis is always characterized by the growth of tubercle tissue in and about the joint. Like tubercle tissue in other parts of the body, this tissue may vary in character; and, dependent upon these variations, several types of tubercular arthritis are recognized.

In some cases the most marked feature of the tubercular process is the degeneration of the tubercle tissue and of the adjacent joint structures with the formation of ulcers. This is known as the ulcerative form of the disease. In other cases the growth of granulation tissue is very extensive, and the name 'fungous' is applied to this form of the disease. In still others extensive suppuration occurs, pus being present in the joint cavity and in the surrounding tissues. This is designated suppurative tubercular arthritis. The tubercular process frequently spreads to and involves the bone, resulting in extensive changes in the bones themselves. Tubercular arthritis is usually slow in its progress. The large joints are most frequently affected. The amount of stiffness is dependent upon the extent of the process. Tubercular arthritis may occur as part of a general tubercular infection, as secondary to other tubercular lesions, or, not infrequently, is confined to a single joint with no evidence of any tubercular condition in other parts of the body.

Treatment of synovitis or arthritis depends upon the cause. In the acute serous or serofibrinous varieties, rest, alternate hot and cold affusion, extension of the limb so as to separate the surfaces, and exercise with the joint immovable, may be all that is necessary. In some cases passive motion is desirable, to break up adhesions, after prolonged rest in a splint. In some exudative, especially in suppurative cases, the joint is aspirated and the fluid drawn off. Rheumatic and gouty arthritis yields to the salicylates, alkalies, lithia salts, or other internal medicine used in rheumatism or gout. In tubercular cases the joint is opened and the tubercular nidus scooped out, or the joint is resected in some instances. Deforming arthritis usually leaves permanent deformities. Sometimes operative procedures, undertaken after the inflammation has ceased, will correct these deformities in part. Consult Marsh, *Diseases of the Joints and Spine* (London, 1895); "Joints, Diseases of," in *Encyclopædia Medica*, vol. vi. (Edinburgh, 1900).

SYNTÁX. A division of philology (q.v.).

SYNTAX, FIGURES OF. Intentional deviations from the ordinary construction of words. The principal figures of syntax are as follows: Anaphora is the repetition of the same word or grammatical form at the beginning of several successive clauses, as '*without* tumult, *without* arms, *without* harm or injury the insurrection was quelled.' Anastrophe consists of a transposition of words, as *rolled the thunder* for *the thunder rolled*, or 'he travels earth *around*.' Asyndeton is the ellipsis of a conjunction or connecting particle, as *veni, vidi, vici*, 'I came, I saw, I conquered.' Brachylogy is the use of a concise or pregnant mode of expression, as 'the eye of a horse is bigger than an elephant,' i.e. than (the eye of) an elephant. Chiasmus is a cross-wise arrangement of words, where the words of a second and corresponding set are stated in inverse order to those of the first set, as 'Begot by butchers, but by bishops bred.' Ellipsis is the omission of a word or words necessary for the construction of the sentence, but not essential to its meaning. By means of ellipsis conciseness and impressiveness are gained, and accordingly it prevails in proverbs, as 'More haste, less speed,' or *Ex pede Herculem*. Asyndeton is a special form of ellipsis. Enallage is the substitution of one part of speech, or of one inflectional form of a word, for another, as 'they fall *successive* and *successive* rise.' Epanastrophe is the repetition of the end of a clause at the beginning of the next, as 'The mouse ran up *the clock, the clock* struck one.' Epiphora is the repetition of a word or words at the end of successive clauses and hence is the reverse of anaphora, as *Lælius navus erat, doctus erat*. Epizeuxis is the emphatic repetition of a word, as

> "*Alone, alone*, all, all *alone*,
> *Alone* on a *wide, wide* sea."

Hendiadys or hendiadyoin is the use of two coördinate words or phrases instead of an expression in which one qualifies the other grammatically, or, in other words, it is the presentation of one idea by means of two coördinate words or phrases, as a 'couch strewn with *purple and tapestry*,' i.e. with purple tapestry, or *armis virisque*, 'with arms and men' (i.e. armed men). Hypallage is the use of one case for another, the transference of an epithet from its proper subject to another, as *Tyrrhenus tubæ clangor*, 'the Tyrrhenian clang of the trumpet,' for *Tyrrhenæ tubæ clangor*, 'the clang of the Tyrrhenian trumpet.' Hyperbaton is the transposition of words or clauses. An example of hyperbaton of clauses is *valet atque vivit*, 'he is well and alive,' for *vivit atque valet*, 'he is alive and well.' Pleonasm is the use of superfluous words, sometimes, however, arising from a desire to secure strength, as in the excessive use of the negative in conversation, especially by uneducated persons or by children. Polysyndeton is pleonasm in the use of conjunctions and is the reverse of asyndeton. Prolepsis consists in introducing a word in advance of its proper place, as 'I know *thee*, who thou art.' Prolepsis also denotes the use of an epithet before it is logically applicable, as *Scuta latentia condum*, 'they conceal their hiding (or hidden) shields.' Syllepsis is the agreement of an adjective or verb with only one of two or more subjects with which it is linked, as *rex et regina beati*. Synesis is a construction of words according to the sense conveyed by them rather than by the strict requirements of grammatical rules, as 'Philip went down to Samaria and preached Christ unto *them*.' Tmesis is the separation of the parts of a word, as in Ennius's famous line, *saxo cere comminuit brum*, or, in 'the love of God *to* us *ward*.' Zeugma is the use of a word in two or more connections, though, strictly speaking, it is applicable to only one of them.

SYNTHESIS (Lat. *synthesis*, from Gk. *σύνθεσις*, composition, combination, a putting together, from *συντιθέναι*, *syntithenai*, to combine, put together, from *σύν*, *syn*, together + *τιθέναι*, *tithenai*, to put, place). In philosophy, a term applied to the organic unity of different elements, or to the process whereby such a unity is constituted. See ANALYSIS.

SYNTHESIS, CHEMICAL. The building up of compounds from their elements. The synthetic methods of chemistry are of the greatest importance in several respects. First, they may serve to test the correctness of analyses, or even, in certain cases, replace analytical methods altogether. For example, if there were any doubt as to water being composed of eight parts of

oxygen and one of hydrogen, or if water could not be analyzed at all, its exact composition could be demonstrated by causing oxygen and hydrogen to combine. In fact, it was the synthesis of water by Cavendish that first indicated its chemical nature and exact composition. (See CHEMISTRY, historical section.) Secondly, synthetic methods may, and very often do, serve to reveal the complex chemical constitution of compounds of carbon. It is explained under CARBON COMPOUNDS (q.v.) that one of the basal principles employed in determining the constitution of compounds is the assumption, itself well founded on facts, that when a given compound undergoes a moderate chemical change, the greater part of each of its molecules remains unaffected: an atom, or a group of atoms, may be replaced by another, but the linking of the remaining atoms is not changed. Thus, by the action of chlorine on acetic acid, the latter may be gradually transformed into mono-chloracetic acid, di-chloracetic acid, and tri-chloracetic acid, one, two, or three atoms of hydrogen in the molecule of acetic acid being replaced by one, two, or three atoms of chlorine; but the remaining atoms (carbon, hydrogen, and oxygen) are linked in the chloracetic acids in the same manner as in acetic acid itself. On this principle, the constitution of a compound becomes known if it is produced by synthesis from compounds of known constitution. In this connection it may be well to observe that the definition of the term synthesis must not be taken to mean the production of compounds from their elements directly. Thus, when it is said that ordinary alcohol can be produced synthetically, it does not mean that alcohol can be made by the direct union of carbon, hydrogen, and oxygen. The synthesis of alcohol consists of the following steps: carbon and hydrogen are caused to unite into acetylene (q.v.); acetylene is caused to unite with hydrogen into ethylene; ethylene is caused to unite with sulphuric acid to form ethyl-sulphuric acid; and the latter by reaction with water yields alcohol. The two compounds employed, viz. water and sulphuric acid, can also be made by starting with their elements; and so it may be said that ordinary alcohol can be made with nothing to start with but elementary substances, and this is what is meant by 'the synthesis of alcohol from its elements.' Finally, many synthetic processes have acquired great importance industrially. In 1868 Graebe and Liebermann built up by synthetical processes the substance called alizarin (q.v.), which occurs naturally in madder root, and which gives the latter its chief value as a dye-stuff. This artificial alizarin is now made on an enormous scale and has almost entirely displaced madder in dyeing and calico-printing. In 1880 Adolf Baeyer accomplished the synthesis of indigo. In 1887 Ladenburg succeeded in the synthesis of coniine, $C_8H_{17}N$, the poisonous alkaloid found in hemlock. Vanillin, the aromatic flavoring principle of the vanilla bean, has been made artificially by several chemists. Antipyrin, a substance much used in medicine, and saccharin, a substance several hundred times sweeter than sugar, are entirely the products of synthesis.

Yet while most of the known carbon compounds can be produced synthetically, some of the most important organic substances, including the proteins and many carbohydrates, still remain unsynthesized, and hence but imperfectly understood, and must still be obtained ready-made from nature. The synthetic methods employed in the preparation of a large number of carbon compounds are mentioned under the special names of those compounds. For further information, consult: Berthelot, *La synthèse chimique* (Paris, 1876; Ger. trans., Leipzig, 1877); Louise, *Synthèse d'hydrocarbures, d'acétones, d'acides, d'alcools, d'éthers et de quinones dans la série aromatique* (Paris, 1885); Lellmann, *Principien der organischen Synthese* (Berlin, 1887); and especially the excellent work of Elbs, *Die synthetischen Darstellungsmethoden der Kohlenstoff-Verbindungen* (Leipzig, 1889-91). See CHEMISTRY (historical section) and CARBON COMPOUNDS.

SYNTHETIC GEOMETRY. See GEOMETRY.

SYNTONIN (from Gk. *σύντονος, syntonos,* stretched tight, from *συντείνειν, synteinein,* to stretch tight, from *σύν, syn,* together + *τείνειν, teinein,* to stretch). A protein substance prepared by the action of dilute acids on the myosin of the muscles. The acid solution thus obtained is neutralized with alkali and the precipitated syntonin is washed with a small quantity of water. Syntonin may be converted into a globulin probably identical with myosin, by dissolving in lime-water, adding ammonium chloride, then neutralizing with acetic acid; from the solution thus obtained the globulin may be precipitated by adding the solution slowly to a large amount of distilled water. Syntonin is soluble in lime-water and in dilute solutions of sodium carbonate, but not in acid sodium phosphate. It may be classed with the so-called acid albumins, and it is distinguished from other substances of the same class of proteids by its insolubility in acid sodium phosphate solution.

SYPHAX, sī'fāks (Lat., from Gk. *Σίφαξ*). A Numidian prince, who played a part in the Second Punic War, an enemy of Masinissa (q.v.).

SYPHILIS (from *Syphilus,* in the Latin poem entitled *Syphilus, sive Morbi Gallici libri tres,* by the Italian physician and poet Hieronimo Fracastoria (1483-1553), a shepherd who was afflicted with the disease by Apollo as a punishment for offering homage to his king instead of to the god; of uncertain etymology, popularly explained as from Gk. *σῦς, sys,* hog + *φίλος, philos,* loving, or, less plausibly, from *σύν, syn,* with + *φίλος, philos,* loving), or LUES, or THE POX. A specific contagious disease peculiar to the human species, chronic in its course, and generally acquired during sexual congress. It is always due to contact with a syphilitic individual or with his secretions or discharges. Descriptions of syphilis are found in the earliest writings, and traces of it are discovered in the bones of prehistoric people. Chinese accounts of it date back to the writings of Hoan-Ti, who lived about 2637 B.C. The earliest Indian record is found in the Ajwe Veda of Suśrutas, A.D. 400. The Japanese historians described the disease several thousand years ago. The Hebrews were familiar with it and it is probable that many cases called leprosy were really syphilis. Hippocrates and his successors describe it as it existed among the ancient Greeks, and Celsus speaks of it among the Romans. Although the malady is known to have existed in Europe at least as early as A.D. 1250, when Theodoric, a Dominican monk, wrote of the *malum mortuum*

and recommended inunctions of mercury for its cure, its authentic and general recognition dates from a severe outbreak of the disease in the army of Charles VIII. of France during the siege of Naples. It was known as 'the Neapolitan disease' and as the *morbus Gallicus*. The disease spread with frightful rapidity and virulence, and during the following years was so widely disseminated as to be considered a form of plague. The armies of the various countries were nearly decimated, and no class of society escaped its ravages.

It was not at first recognized as a venereal disease. Its true nature appears to have been unsuspected at this time, as it was again a little previous to the time of John Hunter (q.v.), after whom was named the Hunterian or hard venereal sore. Hunter, although the greatest surgical philosopher of the eighteenth century, believed that there was but one venereal disease; that gonorrhœa, chancroid, and syphilitic chancre were merely variations of the same constitutional affection. Nearly half a century later (1831) Ricord established the identity of gonorrhœa, but failed to distinguish between chancroid and chancre. This was left to one of his pupils, Bassereau, to accomplish in 1856. The severe epidemics of the fifteenth century have never been repeated, although syphilis has since prevailed with continually decreasing virulence. This is due in part to improved personal hygiene, better understanding of the disease, and rational treatment, but also doubtless to the fact that successive generations have transmitted a certain degree of immunity to their descendants. See IMMUNITY.

The nature of the morbific principle—the *materies morbi*—of syphilis has not been determined. No specific microörganism has been discovered. Syphilis is peculiar to man. Attempts to inoculate the lower animals, with the possible exception of the monkey, have been uniformly unsuccessful. A disease somewhat resembling syphilis is observed in the horse. This is known as *maladie du coit* or equine syphilis. The negro race is believed to be more susceptible to syphilis and to have it in a severer form than the Caucasian. This may be explainable on the ground that the disease is a comparatively new one to the darker race, which has not had time to acquire immunity.

Syphilis requires for its transmission contact of the specific poison existent in the secretions or discharges of a syphilitic patient with an abraded surface of skin or with a mucous membrane. The blood is also capable of transmitting syphilis. Although the disease is as a rule acquired through sexual intercourse, *syphilis insontium*, or syphilis of the innocent, is of frequent occurrence. Physicians may become inoculated by contact with syphilitic patients, and innocent patients, on the other hand, may be infected, though rarely, by surgical and dental instruments. The saliva of syphilitic individuals contains the specific virus, and in this way inoculation may occur by kissing, and the use of pipes, spoons, cups, pencils, sticks of candy, plugs of tobacco, etc. Great care is necessary when one member of a family is affected to prevent transmission of the disease to others, since in the familiar intercourse of relations great danger exists.

After the poison of syphilis has been absorbed a certain time elapses before its effects become manifest. The abrasion heals over and there are no visible signs of danger. This is the period of incubation and lasts on the average three weeks, but may vary from ten to seventy days. At the end of this period a hard thickening appears at the site of inoculation, and this soon breaks down into a discharging sore or ulcer, the discharge from which is extremely contagious. This ulcer is situated on an indurated base and is surrounded by dense tissue, and from this fact is known as the 'hard' chancre. It is the characteristic initial lesion of syphilis, and is usually single. Another period of apparent quiescence now ensues, during which the patient is conscious of no trouble besides the sore. This is the so-called secondary incubation period, lasting from four to six weeks or perhaps longer. A characteristic set of symptoms now appears. The poison has been absorbed by the lymphatics, and upon examination the glands of the groin, axilla, neck, and in fact of the entire body will be found enlarged and indurated. A rash, somewhat resembling that of measles, breaks out upon the chest and abdomen, spreading thence to the face, extremities, and back. The rash may vary widely in character, presenting in different cases macules, papules, nodules, scabs, vesicles, or pustules. The eruption is usually superficial and fades gradually without scarring, differing in this respect from the tertiary rashes or 'late syphilides.' The rash marks the secondary stage of syphilis, and is attended with constitutional disturbances. There is slight fever, with severe nocturnal headache, pains in the bones, and general malaise. The tonsils, soft palate, and lymphatic tissues of the pharynx become swollen, and together with the gums, tongue, and inner side of the cheeks are the seat of 'mucous patches.' These are small grayish or whitish papules or shallow ulcers which discharge a most infectious material. It is through them that by far the greater number of cases of 'innocent' syphilis occur. Mucous patches are also apt to appear on the inner surface of the nose, the eyelids, about the genitals and arms. The throat is sometimes so sore and painful that eating solid food becomes impossible. Coincident with these changes in the skin and mucous membranes, several other tissues are affected. The periosteum covering the tibiæ, skull, clavicles, or sternum becomes the seat of inflammatory thickenings or nodules (see NODE), tender to the touch, but soon disappearing. The joints may swell. The hair may come off in considerable quantities, either in patches, or as a general thinning. The finger-nails are dry, brittle, and lustreless. The lymph glands continue swollen during the secondary period of the disease. They may be felt in chains along the neck and groins. A small gland just above the inside of the elbow, the epitrochlear, is almost invariably affected in syphilis and rarely in other diseases, and is therefore a valuable aid in the diagnosis of doubtful cases. Syphilitic iritis is apt to occur during this stage. It usually affects one eye at a time, and is manifested by photophobia, irregularity of the pupil from adhesions of the iris, swelling, and congestion. Later in the disease other eye tissues—the choroid and retina—may suffer seriously. Deafness may result from infiltration of the labyrinth of the ear.

The period of the active manifestations of syphilis, embracing the primary and secondary stages, extends over a year or more. In many cases all symptoms disappear, and no further evidence of the disease is felt. Patients rarely die during the second stage. After an interval of months or years, in a certain proportion of cases, the so-called 'tertiary' or third stage of syphilis sets in. Insidious degenerative changes may have been going on during the interval and now become manifest, suddenly or gradually. The characteristic lesion of this stage is the gumma, which consists of a soft elastic tumor composed of cells and fibrous tissue. Gummata may develop in any situation, skin, bones, liver, testes, kidneys, lungs, or brain, and vary in size from a hemp-seed to a walnut. They are very prone to break down and ulcerate, often resulting in great loss of tissue and hideous scars and deformities. The bony framework of the nose is frequently destroyed in this manner. The skin is apt to be the seat of a variety of deposits which tend to form sluggish ulcerations, slow in healing, and leaving scars surrounded by deeply pigmented skin. Several disorders of the nervous system are referable to syphilis; some, like hemiplegia, due to syphilitic degeneration of the arterial walls; others, like localized paralysis and convulsions, to gummata on the surface of the brain or the roots of the nerves; others again, like locomotor ataxia, are only indirectly traceable to syphilis.

Congenital syphilis shows itself in many and curious ways. Children born of parents suffering from syphilis in the first or second stage may be infected with the disease. The infection may be derived from the father alone, the mother being healthy; or from the mother alone, the father being healthy; or from both father and mother. Or the mother may acquire syphilis after conception and convey it to the child *in utero*. A curious law, to which there seems to be no exception, is that if a child inherits syphilis from its father, the mother being originally healthy, the infant may infect a wet nurse, but not its own mother, who is in some way protected against infection although she may have shown no evidences of the disease. As a rule the effect of syphilis in the parents is to cut pregnancy short, with resulting miscarriages, premature or still birth. Children may be born alive, presenting lesions of any stage of the disease. In many cases the child is at birth apparently healthy, fat and plump, but in a few weeks develops a characteristic catarrh, vulgarly termed the 'snuffles,' shows a rash, with ulcerations about the lips, genitals, and anus, and gradually wastes away until the face acquires a typical withered, shrunken, and aged appearance. Most of these children die in infancy.

The treatment and prophylaxis of syphilis is a matter of great importance, since there is no disease so widespread in its dissemination nor so potent in its influence upon the human species. Prevention depends on education in matters of sexual hygiene on the part of the public, elevation of the moral tone of the individual, and in segregation and inspection of prostitutes. The latter is practiced with good results in many cities of the Old World, and attempts are constantly making toward the same end in the United States. Great ignorance prevails among the laity as to the nature, effects, and treatment of syphilis. The only remedies of any value are mercury and iodides; but these must be given with care and under close observation, and should be combined with tonic remedies, according to the needs of the particular case. Lay medication is apt to be ineffectual, if not dangerous. Mercury may be given by inunction, fumigation, hypodermically or by the mouth. Excessive doses of mercury are likely to produce a series of very unpleasant symptoms (see MERCURY; SALIVATION), and its unwise use in the hands of the ancient practitioners has resulted in a popular distrust of the drug. As a rule mercury is of greatest value in the first stages of syphilis, a combination of iodine and mercury in the second stage, and iodine alone, usually in the form of potassium iodide, in the tertiary period. When these drugs are given skillfully and for proper periods of time, there is every reasonable prospect of a permanent cure. The time of treatment should extend over at least two and one-half years after all visible signs of the disease have disappeared and marriage should be prohibited during this interval. The general health must be watched, and exercise in the open air, full diet, and appropriate tonics administered. In the syphilis of infants mercury is best given by inunction. Children somewhat older may take mercury in the form of gray powder in small doses. The two other drugs that seem to exert almost a specific effect in children are cod-liver oil and the iodide of iron. For a fuller description of this disease, consult: Lydston, *A Text-book on the Genito-Urinary, Venereal, and Sexual Diseases* (Philadelphia, 1900); Fournier, *Syphilis and Marriage* (trans. by Morrow, New York, 1881); id., *Danger social de la syphilis* (Paris, 1901).

SY'RA (Lat. *Syrus*, from Gk. Σῦρος). An island in the Ægean Sea, belonging to the Cyclades, and situated nearly in the centre of the group, 10 miles southwest of Tinos. Area, 31 square miles (Map: Greece, F 4). It is for the most part barren and rocky, and its natural products are insufficient to support its population. Its importance is due to its being the site of Hermopolis (q.v.), the capital of the nomarchy of the Cyclades and one of the chief commercial ports of Greece. Population of the island in 1896, 26,856.

SYR'ACUSE (Lat. *Syracusæ*, from Gk. Συράκουσαι, *Surakousai*). Anciently the most famous and powerful city of Sicily, situated on the southeastern coast of the island, 33 miles south-southeast of Catania. It was founded by a body of Corinthian settlers under Archias, one of the Bacchiadæ, near the end of the eighth century B.C. The traditional date, B.C. 734, rests on uncertain evidence. The original colonists seem at first to have occupied nothing more than the little isle of Ortygia, about one mile long and half a mile broad, which lies near the shore, but with the growth of the city the population soon passed over to the mainland. This settlement was on Achradina, at the eastern end of a high triangular plateau, which lies north of the island. To the north of the island lay the small harbor, while to the west was the great harbor, one of the best in Sicily. Later the greater part of the city was on the mainland, with which Ortygia was connected by bridges or a causeway. It consisted of Achradina, occupying the

eastern end of the tableland and the adjacent coast, Tyche and Neapolis to the west of Achradina and of Epipolæ, still farther west, with the strong fort of Euryalus at the apex of the triangle. The colony rapidly rose to prosperity, and was enabled to establish sub-colonies of its own, Acræ (B.C. 664), Casmenæ (B.C. 644), and Camarina (B.C. 599). Nothing definite is known of the early political state of Syracuse, but the government seems to have been in the hands of the descendants of the Dorian colonists, who were land-owners employing a large body of serfs, seemingly Sicels. The commerce of the city brought, however, a large 'Demos' of Greeks, who about B.C. 486 expelled the 'Gamori,' or ruling oligarchy, and established a democracy. The 'Gamori' were brought back in the following year by Gelon (q.v.), tyrant of Gela, who at the same time made himself master of Syracuse. He was a great ruler, and under him the city increased in size and wealth. He was succeeded by his brother, Hiero I. (q.v.) (B.C. 478-467), whose court became a literary centre. In B.C. 465 the democracy expelled his brother and successor Thrasybulus, and for sixty years a free and popular government was enjoyed under which Syracuse prospered greatly. The Sicels were reduced, and war was waged with neighboring States, till the island attracted Athenian intervention, only closed by the Peace of Hermocrates (B.C. 424). Renewed hostilities with Segesta led to the great struggle with Athens (B.C. 415-413), in which Syracuse, aided by the Spartan Gylippus, annihilated the invading army, and contributed not a little to the outcome of the Peloponnesian War. But a new power appeared on the stage—the Carthaginian, whose conquests in Sicily toward the close of the fifth century threatened the existence of Syracuse. The successful leadership of Dionysius the Elder (q.v.) enabled him to become tyrant of the city and make it the chief power of Magna Græcia and Sicily. It was he who constructed the docks in the greater and lesser harbors, and surrounded the city with fortifications. His fierce and victorious war with Carthage (B.C. 397) raised the renown of Syracuse still higher. The reigns of Dionysius the Younger (q.v.) and of Dion (q.v.) were unsettled; but after the restoration of public liberty by Timoleon (B.C. 343) a brief season of tranquillity ensued, during which the prosperity of the city rapidly revived. Under Agathocles (q.v.), however, the despotic form of government was again established (B.C. 317). This reign was marked by a war with Carthage, including an invasion of Africa, conducted with very doubtful success. In B.C. 275 Hiero II. (q.v.) was chosen general, and about B.C. 270 he assumed the title of King. He adopted the policy of loyal alliance with Rome, and preserved the independence of the State until his death in B.C. 216. His grandson, Hieronymus, joined the Carthaginians, and in consequence the city suffered a long siege, rendered famous by the devices of Archimedes, and was finally stormed and plundered in B.C. 212 by Marcellus.

Under the Romans Syracuse slowly but steadily declined, though it always continued to be the capital and first city of Sicily, and was made a colony by Augustus. Captured, pillaged, and burned by the Saracens (878), it sank into complete decay, and is at present confined to its original limits, Ortygia, which, however, is no longer an island, but a peninsula. The population of Syracuse, which is the capital of a province of the same name, was about 32,000 in 1900. The mainland contains the chief remains of antiquity, which include a fine rock-cut theatre, a Roman amphitheatre, the great altar of Hiero II., the remains of the ancient fortifications, and the great Latomiæ or quarries. The cathedral on Ortygia has been built around an ancient Doric temple, and the columns of the temple form part of the church. The museum contains many interesting remains of the pre-Hellenic population, found in graves and caves in the neighborhood. In the southern part of the town is the famous fountain of Arethusa. Consult: Freeman, *History of Sicily* (Oxford, 1891-94); Holm, *Geschichte Siciliens* (Leipzig, 1870-98); Cavallari and Holm, *Topografia archeologica di Siracusa* (Palermo, 1883), and *Appendice* (1891).

SYRACUSE. The fourth city in population of the State of New York, and the county-seat of Onondaga County, 148 miles west of Albany and 149 miles east of Buffalo (Map: New York, D 2). It is situated at the mouth of Onondaga Valley, 35 miles south of Lake Ontario, in an amphitheatre of hills.

Syracuse has superior facilities for transportation, steam railroads entering the city from ten directions, and canals from three. The Erie Canal, which pierces the heart of the city, gives water communication with Lake Erie and the Hudson River, and thence with tidewater, and the Oswego Canal with Lake Ontario and the Saint Lawrence. All the steam railroad lines centring here are of two systems, the New York Central and Hudson River and the Lackawanna. The street railway system comprises 65 miles of track, and reaches all sections of the city. It is practically under one management.

The chief residential streets are profusely shaded, presenting a park-like appearance. Syracuse has forty-five public parks, ranging from small plots at street intersections to Burnet Park, on a hillside to the west, with more than 100 acres. Lincoln Park, a wooded height of 20 acres on the eastern border, commands the most extensive and picturesque view of the city and its surroundings. The State Fair, under the auspices of the State Agricultural Society, is permanently located in Syracuse. The State annually appropriates a large sum for the support of the fair.

The buildings of Syracuse University (q.v.) crown a commanding elevation and are among the most imposing edifices in the city. Other prominent public buildings are the city hall, the new high school, costing $400,000, the Carnegie Library, the county court-house, the Federal Government building, the State Asylum for Feeble-Minded Children, the County Orphan Asylum, the Old Ladies' Home, and the four hospitals. The Carnegie (public) Library contains 60,000 volumes, and the Court of Appeals Law Library, belonging to the State, 10,000 volumes. The city also maintains a Museum of Fine Arts. The Onondaga Historical Society is (1904) to erect a building for its own use.

Industrially, Syracuse is fourth among the cities of the State, its establishments in the census year 1900 having $31,358,000 invested capital, and a production valued at $31,948,000.

The leading manufactures are men's clothing, foundry and machine shop products, iron and steel, malt liquors, iron and steel pipe, typewriters and supplies, boots and shoes, agricultural implements, flouring and grist mill products, and furniture. The city is noted for the manufacture of typewriters. The Onondaga Salt Springs, belonging to the State, are on the borders of Onondaga Lake. The manufacture of salt, from the brine pumped out of the springs, was formerly the main industry, and is still of importance. The Solvay Process Works, manufacturing soda ash and other products, and employing some 3000 men, are just outside of the city limits on the west. With its many and varied manufactures, the city has a large wholesale and export trade.

The government is vested in a mayor and common council, elected every two years. The comptroller and treasurer are chosen at the same time. The mayor appoints the heads of departments, including the city engineer, corporation counsel, and commissioners of public works, public safety, and charities. The schools are under the control of a board of education elected on a general ticket. In maintenance and operation the city annually expends about $2,000,000, the principal items being: schools, $350,000; police department, $140,000; fire department, $180,000; and lighting, $122,000. There are 45 miles of paved streets, principally of asphalt; 100 miles of sewers; and 161 miles of water mains. The water system is under municipal ownership and control. The water is obtained from Skaneateles Lake, 18 miles distant, and is conveyed by gravity to the city through 36-inch pipes. The plant cost $5,000,000. The water department in 1902 netted the city a profit of $40,000.

Population, in 1850, 22,271; in 1860, 28,119; in 1870, 43,051; in 1880, 51,792; in 1890, 88,143; in 1900, 108,374.

The territory in which Syracuse is situated originally belonged to the Onondaga Indians. It was visited by the Jesuit missionary Father Isaac Jogues as early as 1642. By treaties in 1778 and 1795 the State bought a large tract containing the salt springs and formed from it the 'Onondaga Salt Springs Reservation,' parts of which were subsequently sold to individuals. Syracuse proper was first settled about 1805 and was of little importance until after the completion of the Erie Canal, its population in 1820 being only 250. Until named Syracuse in 1819 it was known successively as South Salina, Bogardus's Corners, Cassitt's Corners, and Milan. It was incorporated as a village in 1825, and in 1847 absorbed Salina and was chartered as a city. It was prominent for its abolitionist sentiment preceding the Civil War, and was one of the chief stations on the 'Underground Railroad' (q.v.). Here on October 1, 1849, occurred the famous 'Jerry Rescue,' which did much to crystallize abolitionist sentiment in the North and arouse the animosity of the Southern planters. In 1887 the villages of Geddes and Danforth became a part of Syracuse, and in 1892 some further additions were authorized by the Legislature. Consult Bruce, *Memorial History of Syracuse* (Syracuse, 1891).

SYRACUSE UNIVERSITY. A coeducational institution of higher learning at Syracuse, N. Y., founded in 1870. In its academic department it is a continuation of Genesee College, which was conducted at Lima, N. Y., from 1849 to 1871, and in its medical department of the Geneva Medical College (1835-72), which was in part successor of the Fairfield Medical College (1812-39). The university at present comprises five colleges: (1) the College of Liberal Arts with classical, philosophical, scientific, and library courses, leading to the degrees of B.A., Ph.B., and B.S.; (2) the College of Fine Arts, with courses in architecture, belles-lettres, music, painting, art, and decorative design, as well as normal courses, leading to the bachelor's degree in architecture, letters, music, and painting; (3) the College of Medicine, with a four years' course and leading to the degree of M.D.; (4) the College of Law, with a three years' course leading to the degree of LL.B.; and (5) the College of Applied Science with courses in civil, electrical, and mining engineering, leading to the corresponding engineer's degrees. In the graduate department the master's and doctor's degrees are conferred. In addition to the regular departments, the university maintains a summer session of six weeks, and a table at the Marine Biological Laboratory at Woods Hole, Mass. In 1902 an observing station of the United States Weather Bureau was established, in connection with which lectures are given on meteorology and climatology. The attendance in 1903, allowing for duplications, was 2009, distributed as follows: Liberal Arts, 905; Fine Arts, 706; Medicine, 140; Law, 123; Applied Science, 183; Summer School, 39. The endowment was $1,625,600, the income $765,936, and the estimated value of the college property $3,169,361, the grounds and buildings being valued at $1,169,500. The general library contained 50,842 volumes and 21,500 pamphlets.

SYR-DARYA, sēr-där'yȧ, or **SIR-DARIA** (ancient *Jaxartes*). A large river of Russian Turkestan, Central Asia (Map: Asia, F 4). It rises on the north slope of the Tian Shan on the boundary of Chinese Turkestan, and flows in a general northwest direction till it enters the northeastern part of the Aral Sea after a course of over 1700 miles. Its upper course, known as the Nȧrin, descends through a series of romantic gorges as a tumultuous mountain torrent, the fall being more than 3000 feet in less than 50 miles. It receives here numerous tributaries, but after making a long detour to the southwest around the highlands north of Ferghana, it enters upon the great arid lowland steppes, in which it receives no more affluents, but decreases in volume by evaporation. Its course becomes here very sluggish. In the rainy season it overflows the surrounding country, and its low banks are in some places lined with extensive marshes. In these lowland regions, also, a considerable amount of water is drawn from the river through numerous irrigation canals, and the discharge into the Aral Sea is less than half of the volume of the river in its middle course. The delta is marshy and shifting, and the depth on the bar is generally not more than three feet. From its lower middle course the river sends an arm across the desert to the southeastern end of the Aral Sea. This channel is now nearly dry, but probably indicates the former bed of the main river. The river is practically unnavigable in its lower course, though

small Russian gunboats have crossed the bar. It is now little used as an avenue of commerce.

SYR-DARYA, or **SIR-DARIA.** A territory in the northwest of Russian Turkestan. Area, about 195,000 square miles (Map: Asia, F 4). The larger part consists of extensive steppes and deserts. The southeastern part belongs to the region of the Tian-Shan Mountains and rises in some of its snow-covered peaks to an altitude of over 15,000 feet. The flat part of the territory is very scantily watered by the Syr-Darya and Amu-Darya (qq.v.). The lakes are mostly salty. The settlements are found largely at the foot of the mountains, where the streams are utilized for irrigation. Wheat, barley, rice, and cotton are the principal products, the cotton crop being valued at over $3,500,000 in 1900. The nomadic inhabitants have extensive herds of cattle and sheep, and utilize the wool for the manufacturing of woolen products, besides exporting large quantities of the raw material to Russia and other parts of Europe. The Central Asiatic Railway is the principal means of transportation. Population, in 1897, 1,479,848, consisting principally of Kirghizes and Sarts, the Russians forming only about 4 per cent. of the total. Capital, Tashkend (q.v.).

SYRIA. Traditionally, the region lying between the Euphrates River and the Syrian Desert on the east and the Mediterranean on the west, and between the Alma Dagh (the ancient Amanus) in the north and Egypt in the south. This region now forms a part of Asiatic Turkey (Map: Turkey in Asia, G 6). Mesopotamia, or at least a portion of it, is frequently designated as East Syria. Syria proper is now a distinct part of the Turkish Empire and is divided into six provinces—Jerusalem, Lebanon, Beirut, Aleppo, Syria, and Zor. It occupies approximately the area within the above boundaries. It, therefore, includes Palestine. Its area is 109,509 square miles.

Syria proper is traversed from north to south by a system of mountains connected with the Taurus in the north and in the south with Mount Sinai as well as with the important mountain chain of Western Arabia. The loftiest section is the Lebanon district, comprising the range of the Lebanon proper, skirting the middle part of the Mediterranean coast, and the parallel Anti-Libanus, with the valley of Cœle-Syria, between them. The Lebanon reaches an elevation of about 10,000 feet, the highest peak of the Anti-Libanus, Mount Hermon, being about 9000 feet. Syria is in general a plateau of chalk and Tertiary formation, with sandstone in evidence, and varied in places by eruptive stone. The plateau dips steeply to the Mediterranean. It is traversed north and south by the important and remarkable inter-mountain depression which, beginning at the Gulf of Akabah (of the Red Sea) in the south, extends under the name of Wadi el-Araba to the Dead Sea, thence north through the region of the Jordan to its sources, and beyond this through the Lebanon region, becoming narrower but widening again farther north, and finally reaches the sea at Antioch. This depression is over 400 miles long, and generally averages about 12 miles in width. It divides Syria (except in the north and northeast) into two long comparatively narrow stretches of tableland—the eastern and western. For the full description of the western, adjacent to the Mediterranean, see PALESTINE. The eastern strip merges into the Syrian desert, and is sandy and bare, its elevated levels being dominated by the basaltic Jebel Hauran (6000 feet) situated east of Lake Tiberias. The Nahr-el-Asi (ancient Orontes), the Litany (Leontes), and many short streams flow into the sea on the west. The Jordan is the main feeder of the Dead Sea, whose surface is nearly 1300 feet below that of the ocean. The principal affluents of the Jordan are the Yarmuk and Jabbok. In the east are a number of streams that die in the sands of the desert. There are several lakes besides the Dead Sea, the best known being Lake Tiberias (Gennesaret). The climate is that of the Mediterranean basin. At Beirut the mean annual temperature is 68° F.; at Jerusalem, 62.6° F. The rainfall is scanty, being heaviest in the north and west. The springs are short, the summers long, dry, and hot. Snow falls in winter and there is often almost severe cold. The flora is that of the Mediterranean region, the olive being prominent. Forests of conifers clothe portions of the western slope of the Lebanon. But small remnants survive of the famous cedars of Lebanon. In the east and south, however, the plant growth partakes of the scanty desert species. In the extreme north the date palm thrives. Of the wild fauna the lion has nearly disappeared, hyenas exist in some mountainous regions, and jackals abound. Gazelles are still met with. There are several species of venomous serpents, including the cobra. Formerly a land rich and highly productive, Syria is in modern times of very inferior agricultural and industrial significance. Fruits, grain, and vegetables are grown. The principal ports are Beirut and Jaffa. The Syrian Railroad has afforded an impetus to trade since 1895. The population in 1900 was 3,317,600. It is mainly Semitic in race. Mohammedans predominate, and Arabic is generally spoken. Bedouins and Arabs roam in the south and east. The Turks are few. The Christian population is considerable, the Maronites of the Lebanon region alone numbering over 100,000. There are many Jews, especially in Palestine, where they form agricultural communities. The Mohammedan sect of the Druses (in the Lebanon region and the Hauran) has been prominent through its fierce hatred of the Maronites. The chief towns are Damascus, Aleppo, Beirut, and Jerusalem.

HISTORY. About B.C. 1500 the kings of Egypt brought the greater part of Syria under their dominion. Their advance was opposed by the Hittites (q.v.), who were long dominant in northern Syria, and who spread also into the southern part of the country. The non-Semitic people were gradually amalgamated with the Semites among whom they dwelt, their speech becoming Semitic. About B.C. 1000 the Phœnicians were at the height of their power and prosperity and the Hebrew kingdom was firmly established. By this time the Hittites, whose State had become disintegrated into a number of principalities, had begun to feel the power of Assyria. Under David and Solomon the Israelites extended their sway over a great part of Syria, subduing the southern Hittites, the Amorites, and other peoples and subjecting Damascus and other important cities. On the southern part of the

coast the Philistine cities were united in a powerful confederacy. After the disruption of the Hebrew realm Damascus became the seat of a powerful independent kingdom. This was destroyed in the second half of the eighth century B.C. by the Assyrians, who imposed their yoke upon the Philistine cities, and put an end to the kingdom of Israel, while the Phœnician cities paid them tribute. About this time the last of the Hittite principalities were swallowed up by the same enemy. At the beginning of the sixth century B.C. Syria came under the rule of Babylon, which was succeeded in B.C. 538 by that of Persia. In B.C. 333-332 Alexander of Macedon established his sway. At the close of the century Upper Syria was appropriated by Seleucus, one of Alexander's generals, who founded Antioch as the seat of his kingdom. The Ptolemies and the Seleucidæ (q.v.) contended for the possession of the rest of the country, which finally passed to the latter, whose realm, which embraced a large part of Western Asia, came to be known as the Kingdom of Syria. A number of Greek cities were founded by this dynasty. In B.C. 167-141 Palestine threw off the yoke of the Seleucidæ. In B.C. 64 Syria was made a Roman province and in the following year Judea was made tributary to the Romans.

In the third century A.D. the Kingdom of Palmyra, on the eastern borders of Syria, enjoyed a short-lived splendor. After the close of the fourth century Syria formed part of the Byzantine Empire, from which it was wrested in 634-36 by the Saracens. In 661 Damascus became the seat of the caliphs, but about a century later it was supplanted by Bagdad. In the second half of the eleventh century the Seljuks occupied the country. In 1099 the Crusaders took Jerusalem, which was made the capital of a kingdom. At the same time was founded the Principality of Antioch. In the middle of the next century the Christian power in Syra was shattered by the assaults of Sultan Nureddin, whose seat was at Aleppo. In 1174-87 Saladin, Sultan of Egypt, wrested Syria from the successors of Nureddin and overthrew the Kingdom of Jerusalem. In the thirteenth century Khwaresmians and Mongols swept over Syria. In 1291 Acre, the last stronghold of the Christians on the Syrian coast, was taken by the Mameluke ruler of Egypt and Syria. In 1516 Syria was conquered by the Ottoman Turks. In 1831-32 Mehemet Ali of Egypt made himself master of the country, but was forced to relinquish it to the Sultan in 1841. In 1860 there were massacres of the Maronites by the Druses and a frightful slaughter of Christians at Damascus.

SYRIAC LANGUAGE AND LITERATURE. The Aramaic dialect anciently spoken in Edessa and Western Mesopotamia (see ARAMAIC), in which many literary productions have been preserved. This name is derived from the Greek Συρία, which is either an abbreviation of Ἀσσυρία, or a survival of the old designation *Suri* found in cuneiform inscriptions. Before the introduction of Christianity the natives of Mesopotamia called themselves Aramæans. Subsequently this term was used especially for the pagans, while the Christians were designated by Greeks and Persians as 'Syrians' and seem to some extent to have adopted the name themselves. The Syriac language shows in its earliest documents a remarkably fixed type, and must therefore have been long spoken in Mesopotamia. Characteristic of this dialect are the *n* of the preformative in the imperfect of the verb and the loss of the determinative force of the emphatic ending *a* in the noun.

There was probably an extensive pagan literature both in Edessa and in Harran; but no specimen of it has yet been recovered. The earliest document in this language is the translation of the Old Testament, which was probably made by Jews. It may belong to the first Christian century, though it was subsequently revised in some books with the aid of the Greek version. Two recensions of the oldest translation of the New Testament have been preserved in part in a Sinaitic manuscript of the Gospels and a Nitrian manuscript published by Cureton, containing fragments of the Gospels. This latter version may have been made in the middle of the second century. A compilation of the four Gospels, called the *Diatessaron*, was made by Tatian (q.v.), or translated by him from a Greek work of the same kind about 180. This *Diatessaron* is lost and is known chiefly through Ephraem Syrus (q.v.); the Arabic translation of this work published by Ciasca seems to belong to the eleventh century, and has manifestly been made conformable to the standard text. This compilation of the Gospels, after being long in use in the Mesopotamian churches, was finally supplanted by the Syriac Vulgate or *Peshitto* (see BIBLE, heading *Versions*), apparently in the fifth century. The shorter Catholic Epistles (II. Peter, II. and III. John, Jude) and the Apocalypse, which were not found in the old Syriac Bible, were later supplied from the versions of Philoxenus (508) and Thomas of Heraclea (616). In addition to the canonical books, Ecclesiasticus (q.v.) was also translated from the Hebrew and the other Apocrypha, including IV. Maccabees and a part of Josephus's Jewish War called V. Maccabees, were translated from the Greek, as well as several Pseudepigrapha, such as the Apocalypses of Baruch and Ezra. A translation of the Greek text adopted by Origen called the Syro-Hexaplaric version was made by Paul of Tella in 617; and a revision of the New Testament was made by Jacob of Edessa at the end of the seventeenth century.

As early as any of the New Testament translations are the works of Bardesanes, the Gnostic (q.v.), who flourished in the second century and was a poet, philosopher, astronomer, and his-

torian. His *Dialogue on Destiny* is extant; his 150 hymns are lost. A number of Gnostic hymns have, however, been preserved in the *Acts of Thomas*, written in the third century. In the fourth century Aphraates (q.v.) wrote his homilies, and the famous Ephraem (died 373) his commentaries on the Bible and on Tatian's *Diatessaron*, his exegetical discourses, and his hymns. Among the disciples of Ephraem were such writers as Aba, Zenobius, Balai, and Cyrillona. The most flourishing period of Syriac literature extended from c.400 to the Arabic conquest. In the course of the fifth century the great schism occurred which divided the Mesopotamian Church between Nestorians and Monophysites (qq.v.) and severed both from the Catholic Church. Much of the early Nestorian literature is lost; but some works of Hamana (died 607), Babai (died 610), and Elias of Merv remain. Among the Monophysites, Philoxenus of Mabug, Jacob of Serug (died 521), Jacob Baradæus, after whom the party was called 'Jacobites,' and Jacob of Edessa (died 708) were perhaps the most influential writers. In addition to the strictly theological works, there grew up an historical literature, including the *Chronicle of Edessa*, the very excellent chronicle of Dionysius of Tell Mahre, many histories dealing exclusively with the Church, such as that of John of Ephesus (sixth century), martyrologies and legends such as those of King Abgar and the Apostle Addai. Not only theological works, such as the *Clementine Recognitions*, the Apology of Aristides, the ecclesiastical history of Eusebius, and the commentaries of Theodore of Mopsuestia, were translated from the Greek, but also secular works like those of Homer, Æsop, Aristotle, Galen, and Hippocrates. Mana, Moses, Probus, Sergius, and Jacob of Edessa were especially active as translators. After the Moslem conquest the Arabic language gradually gained on the vernacular. But Syriac still continued to be spoken in many localities and to be cultivated as a learned language. The use of two languages led to philological studies, and many works on grammar and lexicography were written. Among these may be mentioned the grammar of Elias of Tirhan and the lexicons composed by Bar Ali Honain (died 873) and Bar Bahlul (963). Many books were translated from the Arabic in the tenth century, such as the *Kalilah wa Dimnah*, *Sindbad*, and Pseudo-Callisthenes's life of Alexander. Classical Syriac was written with great elegance by the Sabian Thabit ben Korrah (died 901) and his sons. (See SABIANS.) With the decline of the caliphate, the Syriac gained a more vigorous life, and numerous theological writers used it. The most important of these are Abulfaraj Gregory, called Bar Ebhraya or Bar-Hebræus (1226-86), who wrote a grammar, a commentary on the Bible, a history of the world, a commentary on Galen, translations from the Greek, essays on ethics and religion, astronomy, and other physical sciences (see BAR-HEBRÆUS); and Abhdisho (died 1318), a learned Nestorian who wrote the history of Syriac literature and many other works. After the fourteenth century there were no noteworthy writers.

The system of writing used by the Edessene Christians before the fifth century was a modification of the Aramaic script then in use in Syria, resembling most the Palmyrene. From the tenth century this writing was known as *Estrangelo*, or 'the writing of the gospel.' The Nestorians continued to use it, while the Jacobites adopted for distinction a cursive form. At first vowels were not indicated at all. Subsequently vowel-letters were used. But in the seventh century the Nestorians began to employ vowel points, and about 700 the Jacobites adopted some of the Greek vowels, which they wrote above or below the consonants to show the proper pronunciation.

The modern Syriac spoken with dialectical differences by the Nestorians in the West, those of Lake Urumiah, in the Kurdish mountains, and on the plain of Mosul, and by the Jacobites of Tur Abdin, exhibits, in addition to numerous Turkish, Kurdish, and Arabic loan-words, certain peculiarities rendering it probable that it is a descendant of the Aramaic, once spoken in Assyria, rather than of the classical Edessene. In the dialect of Urumiah a considerable literature has been developed by American missionaries.

SYRIAC VERSIONS. See BIBLE.

SYRINGA (Neo-Lat., from Gk. σῦριγξ, *syrinx*, pipe, tube; name first given to the mock-orange, because its stems, after removal of the pith, were used as pipes). A genus of plants of the natural order Oleaceæ. The English name of the genus is lilac (q.v.). Syringa is also a name very commonly applied to the mock-orange or Philadelphus.

SYRINGOMYELIA (Neo-Lat., from Gk. σῦριγξ, *syrinx*, a pipe + μυελός, *myelos*, marrow). A disease of the spinal cord characterized by the formation of cavities and the growth of new tissue resembling glioma in its central parts. Its cause is not accurately known, though it may depend upon anomalous embryonic development and it apparently follows infectious diseases as well as wounds upon the hands. It is not caused by alcohol or syphilis, nor is it hereditary. It often appears after childbirth. It is rare, as probably less than 300 cases have been reported. The disease appears between the eleventh and the thirtieth year, and is more frequent in males than in females, in the proportion of 2.2 to 1. The symptoms are pains in neck and arms with reduced sensation in the hands, atrophy of the muscles of the hands, arms, and shoulders, with twitchings, followed by the same wasting in muscles of back, thighs, and legs. The hands become clawed, the feet deformed; and the spine

becomes curved, in extreme cases. Loss of sensation to temperature and pain, while not to touch, occurs, and is considered pathognomonic. Eruptions and ulcerations appear on hands and face, and many other changes occur. The disease runs for from five to twenty years, and the prognosis for checking it is not good. It is incurable. Rest and general tonic treatment, hydrotherapy, and massage, as well as silver and arsenic, are measures tried. Consult: Dana, *Text-book of Nervous Diseases* (New York, 1902).

SYR'INGOP'ORA (Neo-Lat. nom. pl., from Gk. *σῦριγξ, syrinx*, pipe, tube + *πόρος, poros*, passage, pore). A genus of fossil tabulate corals in which the coral mass consists of a bundle of slender cylindrical tubes that rise from a common base and that are connected at intervals by slender hollow horizontal processes or plates. The genus ranges through the Upper Silurian, Devonian, and Lower Carboniferous formations.

SYRINX (Neo-Lat., from Gk. *σῦριγξ*, pipe, tube). A simple instrument of reeds, probably the most ancient of all musical instruments. It is thought to be identical with the Hebrew *Ugab*, mentioned in the Bible. The Greeks supposed it to have been made by the god Pan out of reeds, and hence its secondary name, Pandean pipes. It was formed of seven, eight, or nine short hollow reeds cut in graduated lengths, so as to produce a musical scale, and then fixed together by wax. The lower ends were closed and the upper ones open and on a level, so that the lips could easily pass from one pipe to another.

SYRLIN, zēr'lĕn, JÖRG, the Elder (?-1491). A famous German wood-carver and sculptor, active at Ulm from about 1458, one of the most remarkable masters of his time. The three-seated stool of 1468 at the entrance of the choir in the cathedral, and his chief production, the stately double row of "Choir Stalls" (1469-74) there, the first of their kind in richness and artistic merit, exhibit a plastic beauty unequaled by any contemporary effort. His earliest known work is a "Singing Desk" (1458) in the Museum of Antiquities, and as an isolated production in stone is to be mentioned the fountain in the market square, known as the "Fischkasten" (1482). His son and pupil, JÖRG, the Younger (1455-c.1521), was a worthy inheritor of his art and executed the "Choir Stalls" (1493) and the "Celebrants' Stool" (1496), in the church at Blaubeuren, also a similar stool (1505) in the Neithardt Chapel of Ulm Cathedral, and in the latter the sounding-board of the pulpit (1510), more important architecturally than as a work of sculpture.

SYRPHUS FLY (Neo-Lat., from Gk. *σύρφος, syrphos, σέρφος, serphos*, gnat). A fly of the family Syrphidæ, many species of which are of much economic importance. More than 300 species occur in the United States. They are stout-bodied flies and vary greatly in color. Many species closely resemble bees and wasps. Nearly all of them are flower flies, and carry pollen from one plant to another. Very many syrphus flies in the larval state feed upon plant-lice and other soft-bodied insects. Others live in decaying wood or in manure or soft mud, in the sap of trees or in the stems of plants, or in fungi, or as guests of ants and bumblebees. The rat-tailed maggot (q.v.) is an example of the forms found in soft mud or in manure. Those which live in ants' nests belong to the genus Microdon and are among the strangest insect larvæ known. Those which live in the nests of bumblebees belong to the genus Volucella, and the adult flies resemble bumblebees.

SYR'TIS MA'JOR and **SYR'TIS MI'NOR.** The ancient names of two gulfs on the north coast of Africa. See SIDRA and CABES.

SYRUP. See SUGAR, MANUFACTURE OF.

SYSTOLE. See HEART.

SYSTYLE. An arrangement of classic columns in which the intercolumniation is equal to only twice the diameter of the column.

SYZRAN, sĭz-rän'y'. A river port in the Government of Simbirsk, Russia, on the River Syzran, near the right bank of the Volga (Map: Russia, G 4). It lies in a low district, submerged during the annual rise of the Volga. The town is known as a grain exporting centre. Population, in 1897, 32,377.

SZABADKA, sŏ'bŏt-kŏ. See THERESIOPEL.

SZABÓ, sŏ'bō, JÓZSEF (1822-94). An Hungarian geologist, born in Kalocsa, near Pest, and educated in Pest, and at the School of Mines in Schemnitz. In 1860 he was appointed professor of mineralogy and geology in the university of Pest. Szabó wrote, mostly in Hungarian, on geology, and in 1883 published a valuable text-book of that science, with especial stress on petrography.

SZARVAS, sŏr'vŏsh. A town of Hungary, in the County of Békés, 85 miles southeast of Budapest, on the left bank of the Körös (Map: Hungary, G 3). Population, in 1900, 25,773.

SZÁSZ, säs, KÁROLY (1829—). An Hungarian poet and translator, born in Nagy-Enyed, Transylvania. During the revolution of 1848-49 he fought in the Honvéd army, then studied theology; was engaged in teaching and pastoral work until 1867, when appointed councilor in the Ministry of Public Worship and Instruction. In 1884 he became reformed bishop at Budapest. He was elected to the Hungarian Academy in 1858. Besides numerous lyrics he wrote the epic poems *Almos* and *Salamon*, several dramas, and the tragedy *The Death of Attila* (1888), but won wide reputation especially through his masterly translations of many of the world's great poets, the *Nibelungenlied* and Dante's *Divina Commedia*, also through those embodied in *A világirodalom nagy eposzai* (The Great Epics of the World's Literature, 1882).

SZATMÁR-NÉMETI, sŏt'mär-nā'mĕ-tē. A town in the County of Szatmár, Hungary, 63 miles northeast of Debreczin, on the right bank of the Szamos (Map: Hungary, H 3). It contains a beautiful cathedral. Szatmár-Németi was founded by the Germans in the eleventh century. Its population in 1890 was 21,218; in 1900, 26,881, chiefly Magyars.

SZÉCHÉNYI, sā'chā-nyē, BÉLA, Count (1837—). An Hungarian traveler and explorer, born in Budapest. He traveled in North America in 1863 and in Algeria in 1865, and described the former trip in *Amerikai útam* (1865). In 1877-80 he explored the East Indies, Japan, China, Java, Borneo, Western Mongolia, and the frontiers of Tibet. An Hungarian description of this expedition was published in 1890 and a German version, *Die wissenschaftlichen Ergebnisse der*

Reise des Grafen Béla Széchényi in Ostasien, in 1893.

SZÉCHÉNYI, ISTVÁN (Stephen), Count (1792-1860). An Hungarian statesman, born in Vienna. As a youth he served in the Austrian Army in the wars with Napoleon, and afterwards traveled through Europe. In 1825 he took his seat in the Upper House of the Hungarian Parliament. As a leader of the National Party he endowed the Hungarian Academy of Science, a conservatory of music, and a theatre, and founded a society for effecting improvements in horse-breeding. To his exertions were due the erection of the great suspension bridge between Pest and Buda, the removal of obstacles to navigation at the Iron Gate, the regulation of the Theiss, and the introduction of steamboats on the Danube. In 1847-48 he at first opposed the extreme measures of Kossuth, but later fell in with the popular movement and became a member of the Ministry under Batthyányi and Kossuth in 1848. Becoming insane soon after, he was taken to the asylum at Döbling, near Vienna, where, though he partly regained his health, he spent his remaining years. In March, 1860, his papers were searched by the police, and in a fit of excitement he shot himself. Consult Lónyay, *Graf Stephan Széchényi und seine hinterlassenen Schriften* (Pest, 1875).

SZE-CHUEN, or **SZE-CHUAN,** sĕ'chwän' (Chin., Four Rivers). The largest of the eighteen provinces of China. It is bounded on the north by Kan-su and Shen-si, on the east by Hu-peh, on the south by Kwei-chow and Yun-nan, and on the west by Tibet (Map: China, B 5). Area, 220,000 square miles. With the exception of the elevated plain of Ching-tu (q.v.), 2400 square miles in area, and 1800 feet above the level of the sea, the province is entirely covered with mountains, many of them rising above the snow-line. The eastern portion, east of the Min River, may be regarded as Sze-chuen proper, the western and more inaccessible part being inhabited chiefly by non-Chinese tribes—Man-tse, Si-fan, and Lolos (q.v.). The province is well watered by the Yang-tse and its numerous tributaries—the Yalung, the Min, the T'o, and the Kia-ling from the north, and the Ta-kwan, the Nan-kwang, the Yung-ning, the Chih-shui, the K'i-kiang, and the Kung-t'an from the south. Nearly all of these are obstructed in parts by rapids, but they nevertheless form most valuable avenues of communication in an otherwise difficult country. The climate is not extreme, but changes are sudden. From October to February the country is generally enveloped in deep fogs and the sun is seldom seen. The rainy season begins in May and is at its height in July.

Sze-chuen is rich in minerals, especially in coal and iron, which occur together. Coal is found everywhere, but the seams are thin and the quality does not compare with the coal of Kan-su, Shan-si, Ho-nan, or even Hu-nan. It has not as yet been mined by modern methods. Copper, silver, gold, and lead occur in small quantities. Notwithstanding the mountainous character of the country, agriculture has been brought to a high state of perfection, and the province produces everything needed for home consumption except cotton and wool. The hillsides in many places have been terraced with much industry and skill. Wheat is a winter crop, but it has been largely encroached on by poppy culture, which is more remunerative. Rice, the staple article of diet, is very extensively grown. Other crops are barley, maize, millet, buckwheat, pulse, potatoes, tobacco of very fine quality, tea, sugar, indigo, and sesamum, rape and other oil-producing plants. Hemp is the only textile plant grown, except that used in the manufacture of grass-cloth.

Other important products are silk, white wax, vegetable tallow, tung-oil, rhubarb, medicines, musk, and hides. Wool is imported from Shen-si, Tibet, Kokonor, and other regions. Cotton, both raw and manufactured, comes chiefly from Hupeh. Cotton spinning and weaving are important home industries, and the cloth is exported to Tibet and Yun-nan, along with tea and silk. Iron manufacture from the ores of the province is one of the most extensive industries. Enormous quantities of salt are obtained from brine-springs from 500 to 2000 or more feet in depth, the brine being evaporated by natural gas or coal. It is a Government monopoly, and brings in a large revenue to both the provincial and the Imperial governments. Large numbers of people are also employed in paper-making and the production of fans, umbrellas, crape, gauze, and beautiful silk embroideries, etc.

Sze-chuen can be entered from the east by only two routes: either overland through Shan-si and Shen-si, along difficult mountain paths infested by robbers, or up the Yang-tse by steam to I-chang (q.v.) and thence by native, specially constructed, junks which are hauled slowly and at great expense and risk up formidable rapids and through deep gorges. Within the province itself there are many pack-roads paved with flags, and with steps cut in the rocks at very steep places. For travelers sedans and ponies are used, and for goods coolie carriers. Capital, Ching-tu (q.v.), where resides the Governor-General, who also has charge of East Tibet (q.v.). The only port opened to foreign trade is Ch'ung-k'ing (q.v.). Population, about 70,000,000. The province buys more foreign goods than any other. See Baber, *Travels and Researches in Western China* (London, 1882); Hosie, *Three Years in Western China* (London and New York, 1890); and Bishop, *The Yang-tse Valley and Beyond* (London and New York, 1901).

SZEGEDIN, sĕg'ĕd-ĕn (Hung. *Szeged*). A royal free city of Hungary, next in size to Budapest, in the County of Csongrád, on the right bank of the Theiss a little below the confluence of the Maros, 96 miles southeast of Budapest (Map: Hungary, G 3). The town has been largely and handsomely rebuilt since the terrible inundation of 1879, when 2000 persons lost their lives. A high dike has been constructed to protect the city from another such disaster. The modern streets are wide and there are several attractive squares. Szegedin has a fine rococo town hall, a Gothic cathedral, a handsome theatre, and other stately edifices. The Franciscan monastery contains an excellent library (80,000 volumes) and a museum of antiquities. There are also a Minorite and a Piarist monastery. The principal manufactures are paper, salt, cloth, and the famous Szegedin soap. As the commercial centre of the great Hungarian Alföld it has a brisk

trade in grain, wool, tobacco, lumber, etc., both by rail and river, the Theiss being lined with quays. Boat-building is extensively carried on. New Szegedin lies on the opposite bank. Szegedin was fortified by the Turks, who held it from 1526 for 160 years. Population, in 1890, 87,410; in 1900, 102,991, mostly Catholic Magyars.

SZEGSZÁRD, sĕk'sărd. A town of Hungary, capital of the County of Tolna, on the right bank of the Danube, 84 miles south of Budapest (Map: Hungary, F 3). The town produces an exceptionally fine red wine. Population, in 1900, 13,895, mostly Catholic Magyars.

SZEKLERS. See TRANSYLVANIA.

SZÉLL, sāl, KOLOMAN (1843—). An Hungarian statesman, born in Gosstony, and educated at Budapest and Vienna. Entering local politics in 1867 and Parliament the next year, he so distinguished himself by his financial interpellations that in 1875 he was offered the portfolio of finance by Wenckheim. He retained it until 1878, when he retired because of his disapproval of the Bosnian occupation. He then became president of a great financial institution in Budapest, refusing every inducement to reënter the Cabinet until the fall of Bánffy in 1899, when he rose to the head of the Government as Minister of the Interior and president of the Council. He retired in June, 1903.

SZE-MA KWANG, sĕ'mä'kwäng', or **SSŬ-MA KUANG** (1019-86). A distinguished Chinese statesman and historian, born in Hia, a district of Ho-nan. At nineteen he entered the public service, rose rapidly, became president of the Hanlin Yuan (q.v.), and a Minister of State. He is specially noted for the persistency and the vigor of his opposition to Wang An-shih (q.v.), 'the innovator.' Failing to induce the Emperor to dismiss Wang and repeal his reform, Sze-ma retired to private life, and devoted himself to literature and especially to the preparation of his *History of China* (B.C. 403 to A.D. 960), in 294 books, called the *Comprehensive Mirror for the Aid of Those Who Govern*. In 1085, on the death of the Emperor, he was taken into favor by the Empress Regent, was reinstated in office, and at once set about the repeal of the reforms of Wang, but he died in the following year. Besides the *Comprehensive Mirror*, he was the author of the *Ki-ku-lu*, or Investigations into Antiquity, in 20 books, which extends to A.D. 1067, an etymological dictionary, and many miscellaneous essays. See Rémusat, *Nouveaux Mélanges asiatiques* (2 vols., Paris, 1829), and Giles, *Chinese Literature* (New York, 1901).

SZE-MAO, sĕ'mou'. A town in the southwestern part of the Province of Yun-nan, China, situated 185 miles southwest by west of Yun-nan-fu. The trade of Sze-mao is almost entirely with Burma and Tibet. The town was opened to foreign residence and trade in 1897. Population, estimated at 14,000.

SZE-MA TS'IEN, sĕ'mä' chĕn', or **SSŬ-MA CH'IEN** (c.145-c.85 B.C.). The first great historian of China. He was born in Lung-mŭn, in Ho-nan, made great progress in learning while still a child, and at twenty began a great tour of the Empire. On his return he entered the public service, and was commissioned to inspect and report upon the regions now known as Sze-chuen and Yun-nan, then recently conquered. On the death of his father in B.C. 110 he succeeded him as historiographer, and entered upon the task of completing the great historical work which had been begun by his father. This he accomplished B.C. 91, but the work did not appear until some years after his death. It is entitled *Shih Ki*, or "Historical Records," and in 130 books gives the history of the country from B.C. 2697 to B.C. 104. For specimens of his style, see Giles, *Chinese Literature* (New York, 1901).

SZENTES, sĕn'tĕsh. A market-town of the County of Csongrád, Hungary, on a tributary of the Theiss, 28 miles north by east of Szegedin (Map: Hungary, G 3). The town formerly suffered from inundations, but is now protected by a number of large dikes. Agriculture and fishing are the principal pursuits, and wine is exported. Population, in 1890, 30,797; in 1900, 31,308, mostly Lutheran Magyars.

SZIGLIGETI, sĭg'lĭ-gĕ'tĭ, EDUARD (1814-78). An Hungarian dramatist, whose real name was Joseph Szatmáry. Born at Grosswardein, he studied engineering, but in 1834 went on the stage at Buda and in 1837 became secretary and stage manager of the newly erected national theatre at Pest. Of his numerous dramas several were crowned with prizes by the Academy, among them *Rózsa*, *Vándor színészek* (Itinerant Actors), *Béldi Pál*, *Laczfi Imre*, and *Béla IV.*, but the greatest success attended his popular plays drawn from national life, many of which found their way also to the German stage, notably *The Deserter*, *Two Pistols*, *The Csikós*, *The Foundling*, and others. Besides his excellent *A dráma és válfajai* (The Drama and its Species, 1874), he published biographies of Hungarian actors (1878). He was a member of the Academy and of the Kisfaludy Society, and, since 1874, director of the National Theatre.

SZILÁGYI, sē'lăd-yē, SÁNDOR (1827-99). An Hungarian historian, born at Klausenburg, and educated there and at Maros-Vásárhely. In 1867 he was appointed secretary in the Ministry of Public Instruction, and in 1879 was made librarian of the University Library at Budapest. He founded the Hungarian Historical Society, of which he was secretary until his death, and of whose organ, *Századok* ("The Centuries"), he was editor. He was the moving spirit in the revival of historical interest which took place in Hungary after 1849, published many monographs himself, and edited or projected works of importance. Of these may be mentioned the *Monumenta Comitialia Regni Transylvaniæ*, in twenty-one volumes; a collection of papers from Hungaro-Turkish sources in nine volumes; and a national history in ten volumes (1895-98).

SZOLNOK, sōl'nôk. A town of Hungary, the capital of the County of Jazygia—Great Cumania—Szolnok, 67 miles southeast of Budapest, on the right bank of the Theiss, at the mouth of the Zagyva (Map: Hungary, G 3). On March 5, 1849, the Austrian General Karger was defeated here by the Hungarians. Population, in 1890, 21,094; in 1900, 25,379, mostly Catholic Magyars.

SZUJSKI, shwĭs'kĭ, JÓZEF (1835-83). A Polish historian and dramatist, born at Tarnov, Galicia. He studied in Cracow and Vienna, became associated with Tarnovski in the establishment and redaction of the *Przeglad Polski* in

1867 and was appointed professor of Polish history at the University of Cracow in 1869, subsequently also secretary-general of the Academy of Sciences. In 1881 he was called to a seat in the Austrian House of Lords. He published many mediæval documents and chronicles bearing upon Polish history and in his excellent *Dzieje Polski* (1862-66; new ed. 1896) presented a history of Poland based upon the most recent researches. In German he wrote *Die Polen und Ruthenen in Galizien* (1882). Besides poems and tales he produced a number of historical dramas, remarkable for spirited characterization, such as *Halszka z Ostroga* (1858); *Jerzy Lubomirski* (1863); *Maryna Mniszchovna* (1876); *Jadviga, Kopernikus,* and others.

T

T The twentieth letter of the English alphabet. Its Semitic original *tau*, the last letter of the Phœnician alphabet, meant cross, and was so called on account of the early shape of the character. The various forms which it has assumed are as follows:

Phœnician. Early Greek and Latin. Later Greek and Latin.

As a phonetic character *t* is the voiceless alveolar explosive. To form this sound the tongue-tip is brought into contact with the sockets of the upper front teeth, and the breath is made to escape explosively.

English *t* represents in general an original Indo-Germanic *d*, as Sanskrit *dam*, 'to tame,' Greek *δαμάω*, Latin *domare*, English *tame*. It may also represent an original Indo-Germanic *t*, as in Sanskrit *stigh*, 'to step,' Greek *στείχω*, Anglo-Saxon *stīgan*, English *stile*. An excrescent *t* occurs especially between *s* and *r*, as a glide-sound between the median and lateral positions of the tongue, as in English *stream*, compared with Sanskrit *sravas*. An inorganic *t* has also been developed in some modern English words after a final *s*, as *amidst* from *amiddes*, *amongst* from *amonges*, *whilst* from *whiles*, and in the dialectic *oncet*, *twicet*.

The digraph *th* represents both the voiced and the voiceless spirant, as *then*, *thorough*. It may be pronounced *t*, as *Thames*, *thyme*, as may also the *-ed* of the preterite and perfect participle, as *dressed*. In several words *t* is silent, as in *chasten*, *moisten*, *christen*, *castle*, *gristle*, *hustle*. In *action*, *nation*, *portion*, *ti* has the sound of *-sh*.

As a mediæval numeral T = 160; $\overline{\text{T}}$ = 160,000. In music *t* = tenor, tempo.

TAAFFE, tä'fe, Eduard, Count (1833-95). An Austrian statesman of Irish extraction. He was born at Prague, and was educated in companionship with the Emperor Francis Joseph. He entered the public service in 1857 and was appointed Governor of Salzburg in 1863. He was Minister of the Interior in 1867 and Minister of National Defense in 1868, becoming president of the Council after Prince Auersperg's retirement in September, 1868. He resigned in January, 1870, but three months later became again Minister of the Interior and remained in office until February, 1871, when he was made Governor of Tyrol and Vorarlberg. In February, 1879, Taaffe was once more appointed Minister of the Interior and in August he formed a new Cabinet, over which he presided until 1893. The distinguishing feature of his administration was the greater weight given to the Slav nationalities, especially the Czechs and the Poles, as well as to the clericals, in the public affairs of the Empire and his vain effort to conciliate the divergent nationalities comprised in the Empire. He finally attempted to sustain his Government by a radical electoral reform measure, which displeased all parties, and was compelled to retire in November, 1893. He died November 29, 1895.

TAAL, täl. A town of Luzon, Philippines, in the Province of Batangas. It is on the Transipit River near its fall into the Gulf of Balayán, and is connected by a bridge with Lemeri on the opposite bank (Map: Luzon, E 11). It carries on a large trade in coffee, sugar, and cotton goods in addition to the local industries of agriculture, fishing, and stock-raising. The old town of Taal was situated on the bank of the lake of the same name near the volcano Taal (q.v.), and was destroyed in 1754. Population, in 1897, 22,000, now estimated at about 33,400, of whom a considerable number are of Chinese origin.

TAAL, or Bombón. A volcano in Central Luzon, Philippines. It forms a small island in the middle of Lake Taal, which lies 10 miles southwest of the Bay Lagoon. Its height is only a little over 1000 feet, but it has a crater over a mile in diameter. A number of eruptions have been recorded since the discovery of the islands, the last occurring in 1873.

TAALIBI, tä-lē'bē (Ar. *Abū Manṣūr Abd al-Malik ibn Muḥammad ibn Ismā'il al-Ṭa'ālibī*) (961-1038). A prolific writer upon philological and literary subjects. He was a native of Persia, his birthplace being Nisabur, and he represented the Persian-Arabic school of literature. Arabic philology was now passing from the ancient schools of Basra and Kufa to Persian soil. Portions of Taalibi's works have been edited in Europe and translated, for example: Seligman, *Proœmium et Specimen Lexici Synonymici Arabici Atthalibi* (Upsala, 1863); Cool, *Selecta ex Thaalebii Libro Facetiarum* (Leyden, 1835); Valeton, *Talibii Syntagma Dictorum Brevium et Acutorum* (Leyden, 1844). Consult Brockelmann, *Geschichte der arabischen Litteratur* (Weimar, 1898).

TABAGO, tȧ-bā'gō. An island of the West Indies. See TOBAGO.

TABANIDÆ (Neo-Lat. nom. pl., from Lat. *tabanus*, gad-fly). A numerous family of dipterous insects which live by sucking the blood of horses, cattle, and other animals, and are popularly known as gad-flies, horse-flies, or deer-flies. See GAD-FLY.

TABARD, THE. A famous inn of old London. It was situated on High Street, Southwark, near Kent Road, and must have been in existence as early as the fourteenth century, for Chaucer starts his pilgrims from it on their journey to the shrine of Thomas à Becket. Its sign was a tabard or sleeveless jacket. At the end of the sixteenth century it was in high repute. In the seventeenth century it was damaged by the Great Fire, and in the process of restoration the sign was changed to a 'Talbot.' It was condemned in 1866 and its site is at present occupied by the freight depot of the Midland Railway.

TABARI, tȧ-bā'rē (Ar. *Abū Ja 'far Muhammad ibn Jarīr al-Tabarī*) (838-923). Author of the first universal history in Arabic. A Persian, born in Tabaristan, he studied at Bagdad and visited the other schools in Syria and Egypt. He settled at last in Bagdad, and gave himself to teaching and incessant literary labors. His great historical work is the *Annals*, a history of the world from the creation to A.H. 302. This has been published at Leyden by de Goeje (1879 sqq.). Nöldeke's *Geschichte der Perser und Araber zur Zeit der Sassaniden* (Leyden, 1879) is a translation of portions of the *Annals*. His commentary on the Koran stands superior to all other commentaries. Consult Brockelmann, *Geschichte der arabischen Litteratur* (Weimar, 1898).

TABASCO, tȧ-bȧs'kō. A maritime State of Mexico, bounded by the Gulf of Mexico on the north, the State of Campeche and the Republic of Guatemala on the east, Chiapas on the south, and Vera Cruz on the west (Map: Mexico, M 8). Area, 10,072 square miles. Tabasco is well watered and some of its rivers, as the Usumacinta, are navigable to some extent. The climate is hot and unhealthful and the rainfall very abundant. The fertile soil yields good crops of cacao, sugar, coffee, tobacco, rice, and fruit. Stock-raising is of secondary importance. Population, in 1900, 158,107. Capital, San Juan Bautista.

TABASHEER (Hind. *tabāshir*, Skt. *tavakṣira*, *trakṣira*, bamboo-manna). A substance sometimes found in the cavities or tubular parts of the stems of bamboos and other large grasses. It consists chiefly of silica, with a little lime and vegetable matter, or sometimes of silica and potash. It appears to be formed by extravasation of the juices of the plant, in consequence of some diseased condition of the nodes or joints. It is in high repute among the Hindus as a tonic, and is prepared by imperfect calcination and trituration. Tabasheer has a beautiful veined structure and is remarkable as having the lowest refracting power of any known substance.

TABB, JOHN BANISTER (1845—). An American poet, born in Virginia. He was a Roman Catholic priest and professor of English literature at Saint Charles College, Ellicott City, Md. The verse of Father Tabb is scant, comprising *Poems* (1883), *An Octave to Mary* (1893), *Lyrics* (1897), *Poems Grave and Gay* (1899), and *Two Lyrics* (1900), but it is distinguished for its sympathy with whatever subjects it treats from nature, literature, or religion, for the delicacy and refinement of its sentiment, and for the precision of its verse. *The Sisters*, *To Shelley*, *Clover*, *Indian Summer*, *The Child*, and *The Druid* are examples of his exquisite lyric quality, and of his choice of subject. His thought is generally compressed into a few stanzas, often a quatrain.

TABERNACLE (Lat. *tabernaculum*, diminutive of *taberna*, hut, booth; connected with *tabula*, plank, board, table, tablet, Umbrian *tafle*, on a table). A portable sanctuary which, according to the traditional view, was carried about by the Israelites in the wilderness. The command to build this structure is found in Exodus xxv. 10-xxvii. 19, and the account of its construction in almost identical terms in Exodus xxxvi. 8-xxxviii. 31. While it is called a tent, it was in reality a house, having upright walls made of thick boards on three sides, and a curtain on the fourth. The wooden framework had four coverings, one of linen, one of black goats' hair, one of rams' skins dyed red, and one of the skins of wethers. In front the curtain was fastened to pillars made of acacia wood, with copper bases and capitals covered with gold. This structure was divided into two parts, separated by an inner curtain, supported by four pillars with bases of silver and wholly overlaid with gold. The outer and larger apartment was 'the Holy Place,' accessible to priests only; the inner, 'the Holy of Holies,' was entered only once a year by the high priest. Around the sanctuary was a court inclosed by curtains supported by sixty pillars of wood with bases of bronze and capitals overlaid with silver. In the Holy of Holies stood the Ark of the Covenant; in the Holy Place the table of shewbread, the golden candlestick, and the altar of incense; in the court stood the brazen altar of burnt-offering and around it were ash-pans, shovels, bowls, forks, and fire-pans of brass, while in the middle was the great brazen laver. The tabernacle is described as being of extraordinary splendor and of the costliest materials. It stood in the centre of the camp, and was carried by a large retinue of men when the camp moved. Modern scholars generally regard the description as wholly imaginary and devoid of historical value. It is considered as having been drawn on the basis of Solomon's temple and projected into the Mosaic period. This is indicated not only by the impossibility of such a house being constructed and carried about in the wilderness, but also by the fact that the earlier records know nothing of a tabernacle of this kind, while an Ephraemitish narrative has preserved the picture of a much simpler tent where Yahweh revealed Himself to Moses (Ex. xxxiii. 7 et seq.; Num. xi. 25; xii. 5; xiv. 10). This 'tent of meeting' (*'ōhel mō'ēd*) stood outside the camp and was only a small tent with a single custodian, and Yahweh revealed Himself there in a cloud at the door. It is not impossible that the memory of such a portable shrine, common to many nations, carried about while they were still nomads, survived among some of the tribes that afterwards formed the people of Israel. Apparently the ark

has its own history, and was not originally connected with this tent. The tent plays no part in the early history of Israel in Canaan, while the ark is of great importance.

In the Roman Catholic Church tabernacle is the name given to the receptacle in which the consecrated elements of the Eucharist are retained. By the present discipline, the tabernacle is commonly a small structure of marble, metal, or wood, placed above the altar, and of costly material and workmanship. Even when the exterior structure is of marble or metal, there is commonly an inner receptacle of wood (properly cedar), lined with silk. The tabernacle is appropriated exclusively to the reservation of the Eucharist, and it is prohibited to keep within it any other object. A red lamp is kept constantly burning before the tabernacle.

TABERNACLES, Feast of (Heb. *Khag hasukkōth*). The name given in the Old Testament codes to a festival which marked the close of the harvest of fruit, oil, and wine in Palestine. As a harvest festival it is also known as the Feast of Ingathering (Ex. xxiii. 16; xxxiv. 22) and can be traced back to the Canaanites. The festival was marked by general jubilation and by a visit to some sanctuary, accompanied by sacrifices for the purpose of testifying gratitude to the giver of fertility. Among the popular customs observed by the Canaanites was the erection of booths in the vineyards, in which the people dwelt during the vintage. Hence the name Festival of Booths (or Tabernacles) in the four passages besides those already mentioned in which the ritual is set forth (Deut. xvi. 13-15; xxxi. 10-13; Lev. xxiii. 34-36; 39-44; Num. xxix. 12-40). This Canaanitish agricultural festival was adopted by the Hebrews and in the Deuteronomic and Priestly codes was given an historical aspect by interpreting the custom of dwelling in booths as a reminiscence of the nomadic stage in the life of the people, and more particularly of the traditional forty years' sojourn in the wilderness when the tent formed the only habitation. The pristine importance of the festival may be gathered from the fact that it was called 'the festival' *par excellence* and that originally it was the single occasion in the year on which a pilgrimage to a sanctuary was prescribed. As finally shaped in the Hebrew ritual, it extended over the seven days from the fifteenth to the twenty-second day of Tishri (the seventh month), and in addition the eighth day was observed as a 'solemn assembly,' which in Rabbinical Judaism developed into the festival of 'Rejoicing of the Law.' Booths were erected on the roofs of houses or in the courts and streets, made of olive, pine, myrtle, and palm branches (cf. Neh. viii. 15). The sacrifices prescribed for this feast were more numerous than for any other, sin-offerings (one kid daily) and burnt-offerings (two rams and 14 lambs daily), being prescribed for each day, besides 70 bullocks during the seven days (13 on the first day, 12 on the second, and so on in a diminishing scale). Besides these distinctly biblical enactments, we find in the days of the second temple daily processions around the temple altar, the priestly procession to Siloam to fetch water and its libation in connection with the morning sacrifice (cf. John vii. 37), the singing of the Hallel psalms (Ps. cxiii.-cxviii.), the lighting of the four great golden candelabra in the Court of the Women (John viii. 12), and the carrying of palm branches entwined with myrtle and willow together with a specimen of the *ethrog* (or citron) fruit by the worshipers into the synagogues. The erection of booths and the waving of the palm branches with the ethrog are customs still observed in orthodox Jewish communities. Consult the Hebrew archæologies of Nowack and Benzinger.

TABES DORSALIS, tā'bēz dôr-sā'lis. See Locomotor Ataxia.

TABLATURE (Fr. *tablature,* from Lat. *tabula,* plank, board, table, tablet). A method of musical notation used in the fifteenth and sixteenth centuries. At first it was chiefly employed for the lutes and viols. The lines and spaces of the staff did not represent the pitch of the notes, but the frets of the instrument. Either the lines or the spaces were used, but not both. These lines or spaces varied according to the number of the strings of each instrument. The French and English tablatures denoted the tones by letters, the Italian by numerals. But the German or organ tablatures employed a regular staff and musical notation for the melody or highest part, while the tones completing the harmony were written by letters vertically below each note of the melody. All tablatures had three points in common: (1) All letters or figures belonging to the same chord were written vertically one above the other; (2) all employed lines for the division of the separate bars or measures; (3) all made use of a uniform system to denote the time-value of notes and rests. These signs were written either above or below the numbers or letters. Rests were denoted by a horizontal line placed below the note sign.

TABLELAND. See Plateau.

TABLE MOUNTAIN, or **TAFELBERG,** tā'fel-bērg. A mountain of Cape Colony overlooking Cape Town and Table Bay. It is 3540 feet high and is named for its peculiar shape and level top. It is often covered with a white cloud, which is called the 'Tablecloth.'

TABLES, Lunar. Tabular lists of numerical data based on the elements (q.v.) of the moon's orbit and used for calculating the moon's position on the sky. See Nautical Almanac.

TABLET OF ABYDOS. See Abydos.

TABLEWARE, Silver-Plated. The manufacture of silver-plated tableware originated in England, and the centre of its manufacture was at Sheffield and Birmingham. The industry now flourishes in Germany and also in the United States, where the Rogers Brothers were the first to apply the process of electro-plating with silver to table utensils. This they did in 1846, and in 1851 a company was formed in Hartford, Conn., for the manufacture of electro-plated ware. At the close of the century the silver-plated and

britannia ware industry had spread into seven States, in which were located about 50 factories. Connecticut, however, still led, about one-half the total number of factories being in that State, with an annual product valued at $9,538,397.

Before the introduction of electro-plating, all ware was plated by the application of a thin sheet of silver to the object. Bits of solder were placed here and there between the plating and the body material, and, on subjecting the object to moderate but continued heat, the solder was melted and firmly united the metals. In this process it was always difficult to finish the sharp edges so they had the appearance of a continuous silver surface. The art of fashioning materials by stamping them out with dies (see DIES AND DIE-SINKING) has greatly facilitated and cheapened the manufacture of plated ware. In the modern factory three methods are employed for shaping the body material before the plating is applied—spinning, stamping, and casting, and special parts are sometimes hammered into shape. (See REPOUSSÉ.) The body material used in a standard factory is the composite metal called German silver, which consists of 53 per cent. copper, 31¼ per cent. zinc, and 15¾ per cent. of nickel. Stamping is the method usually employed when a large number of objects after the same pattern are to be made. When only one or a few pieces are to be made according to a given design, they are usually spun. In this process the object is shaped over a rapidly revolving wooden mold, known as a chuck, frequent annealing being required to keep the metal flexible. Spinning requires considerable manual dexterity, while stamping is a purely mechanical process. But the preliminary making of the wooden mold is much easier and cheaper than that of the metal die. Of course only objects which are somewhat spherical in shape can be spun, and the flat metal which is thus molded into shape is stamped out of the sheet. Often the chucks are sectional and hinged, so that they can be removed from the finished object, when this object is narrower at the top than at other portions; but oftener a dish, whether stamped or spun, is fashioned in several sections, which are soldered together before plating. Ornamental borders and similar decorations are stamped separately and soldered on. The final preparation for plating is to remove all roughnesses and scratches from each article and render it perfectly smooth, which is done by sand-finishing.

In applying the process of electro-plating (q.v.) to produce silver-plated ware, the objects are first washed in caustic soda and then in a strong solution of nitric, sulphuric, and hydrochloric acids. The trade terms 'single,' 'triple,' and 'quadruple,' which are commonly applied to plated ware to denote its quality, are somewhat misleading, for the heaviness of the plate usually depends upon the length of time during which the object remains in the electric bath, and not on the number of times the dip is repeated. The ware is carefully weighed before and after immersion and is allowed to remain in the bath until the desired number of pennyweights of silver have been added to its weight, an operation which, in thoroughly good ware, requires several hours, although the vessel is quite as attractive in appearance after a bath of a few minutes. It is sometimes stated that danger of poison is incurred in using certain forms of cheaply made plated ware, but in all but the poorest quality the silver is subjected to so many cleansing processes after it is plated that not a vestige of the deadly poison, cyanide of potassium, in which it has been immersed can remain upon its surface. Standard ware, after it is plated, is finished by a succession of processes of hand polishing and burnishing.

TABOO' (Samoan *tapu*, Hawaiian *kapu*, forbidden). An object or act religiously interdicted, and the religious system based upon such interdiction. Under various names and in one form or another, the practice of taboo is found all over the earth; but it has nowhere else been so systematized as in Polynesia. Primarily, taboo is something forbidden because the tabooed object is regarded as potent to injure owing to its *mana*, or mysterious (spiritual) power, which may be either holy, as a priest's possession, or unclean, as a corpse. There is at first no moral significance in taboo, and in many cases the interdict is due merely to fear of spirits. Thus in New Zealand there are a *mana* taboo and an *atua* taboo, the latter arising from a belief in spirits, *atua*, or a more personal embodiment of *mana*. Even in rites of purification the object is simply to keep off evil spirits. Taboo in many cases reverts to another phase of primitive philosophy, which sees retained in blood, nails, hair, etc., though severed from the body, the spiritual power of the individual. But in some cases taboo is merely the expression of conservatism, which may be religious or social. An instance of the former is the taboo of iron in religious ceremonies. Thus in such ceremonies both the ancient Romans and the modern Pawnee Indians put a taboo on iron, since the gods dislike innovations. Even without the fear of divinities, the same religious conservatism prevents the Australians from using stone implements in circumcision, for which they employ the still more antique burnt-wood knife. But there is also a social conservatism resulting in taboo. Foreigners and new things generally are dangerous and are regularly tabooed by many wild tribes (as in Africa), though the taboo is easily removed except in the case of chiefs. In such cases the foreign person, thing, or act is tabooed because of the unknown and dreaded *mana*. But, on the other hand, there are taboos which are simply in the interest of old practices. Thus the Hindu laws give the bed-hours of kings, and it needs only the right environment of superstition and antiquity to make such laws seem to be the effect of taboo, as in Egypt, though there can be no question that this is not the case in India.

Taboo may be permanent or temporary, private or public. Especially stringent are all royal and priestly taboos, because kings and priests control the weal of the people and must, for the people's sake, be guarded against danger in food and the like. In some cases a king becomes a mere slave bound by the rules thus laid upon him. In others he makes taboos for his own interest. The king is guarded from tabooed acts and objects; but the people too must guard themselves from the mysterious divine *mana* of the king, and it is this latter aspect of taboo which king and priest alike find it for their interest to maintain.

What is not taboo is *noa*, common, and in this antithesis lies the germ of the conception of per-

sonal property as applied to many persons and things. Thus taboo became in many cases merely an assertion of proprietary rights, as may be seen from the fact that a lesser chief's taboo was disregarded in New Zealand by a stronger chief, but a stronger chief's taboo was feared and respected by one weaker. Isolation was the object of taboo and this was the first stage to ownership. Food-taboos are often totemistic or hygienic, and the taboo of knots, which is very common, is a temporary taboo imposed because of the belief in mimetic magic. But it is not necessary that the imitative act be due to a wish to injure. Thus in Africa, Greece, and elsewhere there is a taboo on knots, locks, crossed arms and legs—in short, on all that suggests an impediment. Another common taboo is the *klonipa* or name-taboo of the Kafirs, with the woman-language found among the Kafirs (as also among the Semites and the Caribs), certain names and words being tabooed, for example, the names of fearful beasts in India, of kings in Africa, and of the dead in Australia and elsewhere, as well as words used only by women. Sex-taboo is very common. Thus the belief that a woman's blood is fatal to a man leads at stated periods to a temporary taboo of women even among civilized Hindus, and in many countries men may not eat with women. Other common examples of taboo are as follows: To be ill, or to touch a corpse or grave, a king or a priest, or anything divine (such as royal blood) renders one taboo. A priest's or a king's clothes are so filled with *mana* that it would kill any one else to wear them, and to enter a chief's house or even in some cases to look at a great chief would be destructive. A priest's house is taboo even to himself, so far as eating in it goes. The taboo of part of one's self is often recognized. Thus, when a person is under taboo he may not touch his own head and has to be fed by another or eat with chopsticks. Such a person may not touch a drinking vessel lest he render it also taboo and dangerous. For whatever comes in contact with a tabooed object becomes itself tabooed. The private or public taboo of places for certain practical reasons is also noteworthy. A river is tabooed by a king until the fishing-season is over; a wood, till the game is caught; a field, till the harvest is gathered. A public taboo is where, as in New Zealand, a whole community is made taboo while getting in their crops. This renders it impossible for any member of the tribe to do anything else till the taboo is removed, and prevents any stranger from approaching the tabooed ground. The removal of a public taboo is made by a priest who repeats a spell and performs certain rites over the tabooed people. If a chief wants anything for himself he taboos it by calling it part of himself. Women, if of high rank, may taboo an object as effectively as do chiefs of the tribe.

Taboo has been explained either as a priestly trick or as a religious observance, required by the chief for political reasons. But neither explanation will suffice, though many taboos may be referred to the arbitrary enactment of priest or king, and again some taboos are not religious at all. Others explain taboo as due to a categorical imperative, and deduce from it all moral laws as well as most of the practices of civilized communities, such as caste, the wearing of ornaments, the carrying of umbrellas, the washing of new-born babes, etc. On the other hand, oaths, the punishment of murderers and thieves, and marriage restrictions may be developed out of a taboo system, which recognizes no moral sin, only the danger of 'breaking taboo.' But in that case we have to do not with a categorical imperative, but with a belief in a mysterious spiritual potency and the fear of its effect. An extension of this belief results in its becoming purely formal. Taboo itself then may be divided into purely religious and formal taboo; while, if everything 'forbidden' is to be called taboo, there must be added a mass of detailed regulations arising from different sources, some of them having no connection with what is strictly called taboo; and it is evident that for such a combination of effects there can be no one explanation. Consult: Taylor, *Te Ika A Maui, or New Zealand and Its Inhabitants* (2d ed., London, 1870); Robertson Smith, *Religion of the Semites* (2d ed., ib., 1894); Jevons, *Introduction to the History of Religion* (ib., 1896); Frazer, *The Golden Bough* (2d ed., ib., 1900).

TABOR (Heb. *Thābōr*, lofty place). The most conspicuous and famous mountain in Galilee (Map: Palestine, C 2). Its summit is 1843 feet above sea level. As a typical mountain of the Holy Land it impressed itself upon the language of poetry. It seems to have been the natural site for a sanctuary, and upon it from early times lay a town of the same name. Here Barak assembled his forces to attack Sisera (Judges iv.); twice the Jews held it, though unsuccessfully, against the Romans (B.C. 53; A.D. 67). It is the traditional scene of the Transfiguration of Christ, although most unreasonably, and so it became the site of churches and monasteries, and was an object of pious pilgrimage. Consult: *The Palestine Exploration Fund Memoirs*, vol. i. (London, 1881); Robinson, *Biblical Researches* (Boston, 1841).

TABOR (OF. *tabour*, Fr. *tambour*, Sp. *tambor*, from Ar. *tambūr*, sort of lute with a long neck and six brass strings, drum). A small drum, played with one stick, generally in combination with a galoubet or three-holed fife.

TABOR COLLEGE. An undenominational institution of learning for both sexes at Tabor, Iowa, founded by a company of missionaries in 1857 as an academy, and incorporated as a college in 1866. The courses after the freshman year are arranged in the group system and include instruction in music and art. The attendance in 1903 was 181; the faculty numbered 15, and the library contained 12,000 volumes. The productive funds of the college in the same year amounted to $104,000.

TABORITES. The most radical party of the Hussites in Bohemia. They derived their name from their fortress of Tabor, near the river Lužnič. They asserted the right of individual judgment, rejected all ordinances of the Church not expressly appointed in the Bible, and had democratic tendencies. Their leaders were John Ziska (q.v.), Nicholas of Pistna (Husinec), Procopius the Great, and Procopius the Lesser. (See PROCOPIUS, ANDREW.) At first, in the face of common danger, all parties of the Hussites held together and inflicted repeated defeats upon the Imperial troops. After the Calixtines (q.v.) had made terms with Sigismund and the Church

(1433), the Taborites continued the war, but were overthrown in the battle of Böhmischbrod, May 30, 1434. The remnant of them was absorbed in the Bohemian Brethren (q.v.). See HUSSITES.

TABRIZ, tȧ-brēz', TAVRIS, or TEBRIS. The second largest town of Persia, capital of the Province of Azerbaijan, situated in a wide valley, on the Aji, a tributary of Lake Urumiah, 35 miles east of the lake, in about latitude 38° 4′ N., longitude 46° 18′ E., over 4000 feet above the sea (Map: Persia, B 2). Owing to the many earthquakes, large sections of the town are in ruins. The place is healthful, although the weather is bitterly cold a third of the year. In spite of the altitude, the bare rocks rising on the northeast and east and the peak of Sahand standing on the south give Tabriz the appearance of being shut in by mountains. The squalor of the native huts and the poor sanitary precautions are counteracted by the abundance of water and the numerous refreshing orchards and gardens. The town, in addition to its hundred public baths, numerous caravansaries, and five Christian (Armenian) churches, has over 300 mosques. Among these, the 'Blue Mosque,' incrusted within and without with blue faïence tiles, is especially worthy of mention. The 'Ark' in the centre of the town, the residence of the heir apparent, is a large, somewhat imposing brick building. Its cracked walls bear witness to the frequency and violence of earthquakes in this region. The 'Great Maidan' square and the ample barracks are examples of modern progress. There is an international telegraph. Before the Caucasus Railroad and the Caspian Sea became important mediums of transportation and the Russian trade was diverted to Astara and Resht, Tabriz was the emporium of Western trade.

In 1898-99, according to the books of the custom-house, the exports amounted to £219,930 and imports to £682,330, but it is likely that these figures are much less than the total trade. Dried fruits, silk, and various kinds of manufactures are exported from Tabriz. There are lead mines in the vicinity, and copper and cobalt are found in the Sahand. The population is estimated at from 165,000 to 200,000. It was formerly much larger.

Tabriz is said to have been founded by the wife of Harun al-Rashid in 791, but is mentioned before that date. In 858, 1041, 1721, and 1780 it was devastated by earthquakes. In that of 1721 80,000 persons lost their lives. It was held in turn by the Arabs, Seljuks, Mongols, and Turkomans, from whom it was taken by the Persians. It was several times in the possession of the Turks and was finally taken from them by Nadir Shah in 1730. Tabriz is essentially a Turkish city and Turkish is the prevalent language.

TAB'ULA BANTI'NA. The chief source of knowledge of the Oscan tongue; a bronze tablet in the Naples Museum, containing on one side an Oscan inscription of 33 lines referring to affairs of Bantia, and on the other a portion of a law in Latin. It was found near Bantia in 1793.

TABULA ILI'ACA (Lat., Ilian Tablet). A small relief in soft marble found near the ancient Bovillæ in 1683, and now in the Capitoline Museum at Rome. The slab, 10 × 11½ inches, is covered with scenes from the Trojan War, taken from the *Iliad* and the poems of the Trojan Cycle (see CYCLIC POETS), with explanatory Greek inscriptions. It is generally supposed to have been intended for school instruction, but was probably an ornamental panel of a bookcase.

TAB'ULA'RIUM. A large building on the slope of the Capitoline Hill facing the Roman Forum, built by Quintus Lutatius Catulus in B.C. 78 for the preservation of State records. It rested on massive substructures and consisted of a series of vaults with an upper portico of Doric half columns, some of which are still to be seen. Its extent corresponded with the present Palazzo del Senatore, which is built on the ancient walls. The structure is in good preservation, although the masonry of the vaults is corroded by the action of salt stored in them during the Middle Ages.

TABULAR STANDARD. A proposed standard of value which should obviate difficulties due to changes in the purchasing power of money. The proposal involves the preparation, by public authority, of a table of relative values of certain selected commodities after the fashion of an index number, and the permissive use of this table as a legal standard in contracts involving deferred payments. A tabular standard has been briefly defined as an official index number. Its compilation would require a commission or other body with power and facilities to collect price statistics. Having decided what commodities should be employed as basis for the standard, the commission would then calculate a yearly or monthly index number according to some accepted method. (See article INDEX NUMBERS.) The statistics would of course be public, and any one who chose could verify the calculation. The rise and fall of prices would either be expressed in percentages, or an arbitrary unit would be adopted, whose changing values, expressed in money, would indicate the same thing.

The practical operation of the tabular standard is simple. When a person makes a loan of say $100 for one year, the contract entitles him to receive the same number of dollars (usually with interest) at the end of the specified time, but it does not insure that the $100 which he lent and the $100 he receives will have the same purchasing power. If prices have risen in the interval, his $100 will buy less, if prices have fallen it will buy more. In so far as changed purchasing power is not compensated by a change in rates of interest, debtors are likely to be burdened by an appreciation, creditors by a depreciation, of the value of money. Suppose, however, the tabular standard to be employed, and that A sells a piece of property to B for $12,000, of which ¼ is to be paid at once, and ¼ more at the end of each succeeding year. The $3000 cash is of course paid as such. But after a year the tabular standard might show the purchasing power of money to have fallen 10 per cent. Expressed in tabular units, if at the time of sale a unit was worth $10, it would now be worth $11.11, giving the proportion 10.00 : 11.11 : : $3000 : $3333.33, which last figure is what B will have to pay. If at the end of the second year a unit of the tabular standard was worth $9, B would be called on for only $2,700. Whether he pays more or less in money, the sum will always have a uniform value in terms

of the commodities on which the standard is based.

That many advantages would be gained from the use of a tabular standard has generally been admitted. Two serious practical difficulties stand in the way of its introduction. First, the conservative attitude of business men toward any change of this sort; second, the difficulty of agreeing upon the precise mode of calculating the standard, and especially upon the precise commodities which should be selected as basis. Gen. F. A. Walker and others have questioned with good reason the practicability of the standard for the frequent short-time transactions of ordinary business, but for contracts of long duration, and for correcting injustice to recipients of fixed salaries, there seems no ground to question its suitableness.

The first conception of a general index number, or tabular standard, however, appears to date from 1798, when Sir George S. Evelyn read before the Royal Society a paper on "Endeavors to Ascertain a Standard of Weights and Measures" (*Philosophical Translations*, vol. lxxxviii., pp. 175 et seq.). Evelyn's selection of articles is open to criticism, as was pointed out by Arthur Young in 1811. Joseph Lowe (*The Present State of England*, London, 1822), referring to both Young and Evelyn, proposes the actual introduction of a tabular standard, and discusses the modes of calculating it. (New York edition, 1824, p. 287, and Appendix.) His is the first practical treatment of the subject in English. In Germany the principle of the tabular standard had been suggested about 1805, in application to rent payments. (Horton, *Silver and Gold*, 1877, pp. 39, 157.) G. P. Scrope, in a pamphlet of 1833, and in *Principles of Political Economy* (London, 1833, pp. 405, 424), again proposed the standard. G. R. Porter also treated the subject, and gave a table, in his well-known *Progress of the Nation* (London, 1838 and 1847). The matter was finally brought to prominence by W. S. Jevons, in an essay of 1865, and more forcibly in his *Money and the Mechanism of Exchange* (1875, chap. 25).

BIBLIOGRAPHY. Consult the *Reports of the Committee of the British Association on Measuring Variations in the Value of the Monetary Standard* (*British Association Reports*, 1887, 1888, 1889, 1890; the most important material in English); also Price, *Money and Its Relation to Prices* (London, 1896); Walker, *Money* (New York, 1878); *Report of the Monetary Commission of the Indianapolis Convention*, 1898.

TABULATA (Lat. nom. pl., tabulate, floored, table-shaped). A suborder of fossil corals characterized by the development of distinct horizontal septa or tabulæ across the visceral chambers of the corallites. It includes such genera as Favosites, Pleurodictyum, Michelinia, Aulopora, Syringopora, and others which are important members of the Paleozoic faunas. See CŒLENTERATA; CORAL; and articles on genera mentioned above.

TABULATING MACHINES, ELECTRIC. See CALCULATING MACHINES.

TACAHOUT, tä'kȧ-hōōt' (native name). The small gall formed on the tamarisk tree, *Tamariscus Indica*. Tacahout is one of the sources of gallic acid, of which it contains a large proportion.

TAC'AMAHAC' (South American name), or TACAMAHACA. A name applied to several different resins. One variety of tacamahac is yielded by the balsam-poplar (*Populus balsamifera*) growing in the United States. Another variety is obtained from certain tropical American trees (*Elaphrium tomentosum* and *Elaphrium tacamahaca*). East Indian tacamahac is obtained from the *Calophyllum calaba*, *Calophyllum inophyllum*, and *Calophyllum tacamahaca*. These and certain other varieties are used in making varnishes and to some extent also in medicine. See CALOPHYLLUM.

TACANA, tȧ-kȧ'nȧ. A group of tribes, constituting a distinct linguistic stock, inhabiting the banks of the Upper Beni and Mamore rivers, Northeastern Bolivia. They are remarkable for their light complexion, fine features, and independent expression.

TACCA (Neo-Lat., from the Malay name). A genus of large perennial tuberous-rooted plants of the natural order Taccaceæ. The few species are found in maritime places and woods in the South Sea Islands, tropical Asia and Africa. Some of them (*Tacca pinnatifida*, etc.) are much cultivated for the sake of their starchy tubers, which are used, generally with an acid, as food, although their acridity must be removed by maceration with water. They yield tahiti arrowroot, which is used as a substitute for West Indian arrowroot. The leafstalks of various species are boiled in China and Cochin-China and used as food. Hats, brooms, and other articles of value are made from them.

TACCHINI, tȧ-kē'nē, PIETRO (1838-1905). An Italian astronomer, born at Modena. He was appointed director of the observatory there in 1859, and was transferred to a similar post at Palermo in 1863. In 1879 he became director of the observatory in the *Collegio Romano*. He became known for his observations of eclipses and for his work with the spectroscope. His publications include *Il passaggio di Venere sul sole dell' 8-9 dicembre 1874, osservato a Muddapur* (1875), *Ecclissi totali di sole del 1870, 1882, 1883, 1886, e 1887* (1888).

TACHÉ, tȧ'shȧ', ALEXANDRE ANTOINE (1823-94). A Canadian Catholic archbishop, born in the Rivière-de-Loup, Lower Canada. He joined the Order of the Oblate Fathers, traveled great distances toward the northwest and became known for his mission work among the Indians. In 1871 his see, that of Saint Boniface, was erected into an archbishopric. Archbishop Taché was the founder of the Saint Boniface Theological College, and wrote *Vingt années de missions dans le nord-ouest de l'Amérique* (1866), and *Esquisse sur le nord-ouest de l'Amérique* (1869), which has been translated into English and is one of the most valuable works of reference on the region.

TACHINA-FLY, tȧ-kī'nȧ (Neo-Lat., from Gk. *ταχύς*, *tachys*, swift). A parasitic fly of the family Tachinidæ. These insects resemble in general the common house-fly and as a rule are gray, sometimes striped. They are usually parasitic upon caterpillars, upon the backs of which the females lay their eggs. The maggots penetrate

the body of the victim and feed upon its soft internal organs. Frequently, however, caterpillars cast their skins before the eggs hatch. The tachina-flies are considered beneficial to man.

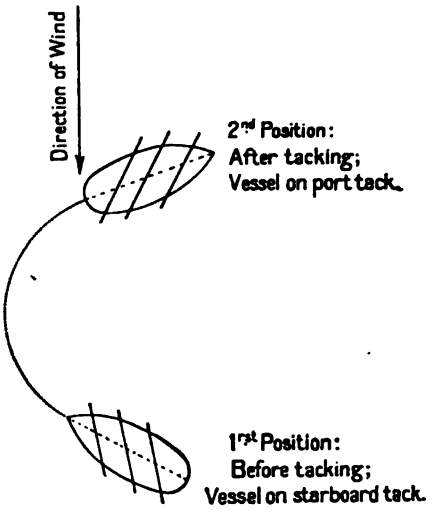
TACHYGENESIS, tăk'ĭ-jĕn'ĕ-sĭs (Neo-Lat., from Gk. *ταχύς, tachys*, swift + *γένεσις, genesis*, origin, production, generation). A term proposed by Hyatt for rapid evolution, or evolution by leaps, i.e. without the vast series of intermediate forms postulated by Darwin. In his own words Hyatt defines tachygenesis as "the law of acceleration in the inheritance of characters." It has been found, for example, that characteristics are inherited in a series of species in a given stock at earlier and earlier stages in the ontogeny of each member of the series. These characteristics, as a rule, altogether disappear from the ontogeny, through lapse of heredity in the last members of a series, and thus the terminal forms become very distinct in their development. Rapid evolution was also very marked at the beginning of the evolution of any stock. In the dawn of geological history, as soon as divergent evolution set in, each type had a more or less free field, and its first steps in evolution were obviously not affected by natural selection. Afterwards evolution became much slower. On the other hand, when the type began to decline there was a sensible quickening of evolution. Dall suggested the term 'saltatorial evolution'; Galton, De Vries, and others, and especially the paleontologists, have all supposed that evolution has often been by leaps or spurts. Consult: Hyatt, "Cycle in the Life of the Individual (ontogeny) and in the Evolution of Its Own Group (phylogeny)," in *Proceedings of the American Academy of Arts and Sciences*, vol. xxxii. (Boston, 1897); Dall, "On a Hypothesis of Saltatory Evolution," in *American Naturalist*, vol. xi. (Boston, 1877).

TACITUS, tăs'ĭ-tŭs, Marcus Claudius (c. 200-276). Roman Emperor (275-276). He was born at Interamna (modern Terni), in Umbria, and was elected Emperor by the senate after the death of Aurelian and an interregnum of seven months (275). He began his brief reign of 200 days at the advanced age of seventy-five years. He instituted needful reforms and favored the restoration of the power of the senate. His victory over the Alani and Goths, for which he took the title *Gothicus Maximus*, is recorded on his coins. He was murdered by the soldiers in Asia about April 12, 276.

TACITUS, Publius Cornelius (c.55-c.117). A Roman historical writer. Information as to his life is exceedingly meagre. Tradition, however, designates Interamna as his birthplace. His training and career certainly indicate that he belonged to a Roman family of good standing. He was prætor in the reign of Domitian and consul suffectus under Nerva. In the year 78 he married the daughter of Gnæus Julius Agricola, a man prominent as a soldier and statesman. This event had great influence on his subsequent career. After his prætorship he was absent from Rome for at least four years until after 93, the year after the death of his father-in-law. The intimacy of Tacitus and Pliny the Younger is proved by references in the letters of the latter, and the two were associated in the successful prosecution of Marius Priscus, proconsul of Africa, charged with extortion. Tacitus's annals were published in 116 or 117, so that we may believe that he lived to the reign of Hadrian. Apparently he looked forward to writing a history of the reign of Domitian and of that of Trajan, but he must have changed his plan, for he began his *Histories* with Galba and continued the work through the reign of Domitian. In the *Annals* he declares his purpose of writing the history of Augustus and in the *Histories* of narrating the reigns of Nerva and Trajan, but we have no indication that he ever carried out this contemplated task. He wrote, however, the history of the Empire from the death of Augustus down to the beginning of his earlier work, i.e. through the reign of Nero.

The earliest extant work of Tacitus is the *Dialogus de Oratoribus*, published about 75 or somewhat later, but not later than the reign of Titus. The *Agricola* followed in the year 98, and even when engaged upon these books the historian was preparing for some greater work. It is possible that his *Germania*, or more fully *De Origine, Situ, Moribus, ac Populis Germaniæ*, represents some of the material accumulated in preparation for some more extensive history. The *Histories* belong to the reign of Trajan and the date of completion may be set in 108. The *Annals* are the last work of the historian and are plainly the production of the fully developed writer. As we have references to the *Annals* in the *Histories*, the date must be later than 108, and as there is apparently a reference in the second book to Trajan's conquest in the East (115-116), the publication may have been just prior to the reign of Hadrian. The *Dialogue on Oratory* belongs to the writer's early manhood, and gives evidence of the influence of Cicero and Quintilian, in so marked a degree that some scholars have attempted to assign it to Quintilian or to some other author not identified. The best opinion of the present day is in favor of the genuineness of the work. The subject is an investigation into the causes of the decline of eloquence, and the discussion is carried on by two celebrated orators of the Flavian period who are respectively supporters of the old and new oratory. After an eloquent silence—eloquent because we know the depth of feeling from the bitter words as to the reign of Domitian found in the introduction—Tacitus wrote the *Agricola*. This work is a gem, a most carefully prepared piece of biographical composition. The rhetorical power of the writer is plainly felt in the closing chapters, which are unexcelled in Latin literature. His *Germania* is a most important work because of the descriptions of political institutions and of the customs of various tribes. As the writer brings into vivid contrast the life of the Germans and that of the Romans, it has been thought by some that he was endeavoring to instruct his countrymen, either pointing out their evil ways, or startling them and warning them against the dangers threatening on their northern frontier. Tacitus shows an exact knowledge of those Germans near to the Rhine, but is uncertain as to the interior and more remote tribes. The greatest work of Tacitus has not come down to us entire, for of the *Histories* there are extant only the first four books and a part of the fifth, so that we have

merely the year 69 and a part of 70. Of the *Annals* there is extant only about one-half, and this does not give a continuous narrative. After the fifth chapter of the fifth book there is a lacuna which marks the loss of the events of 29-31. Tacitus probably ended this book with the death of Sejanus, so that the beginning of the sixth book is also lacking. The seventh to the tenth, the beginning of the eleventh, and the close of the sixteenth are also missing, and we thus lose all of the reign of Caligula, the first five years of Claudius, and the last two years of Nero.

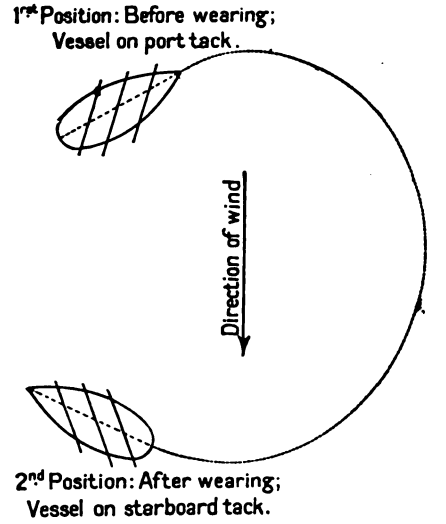


In the *Annals* Rome and the Princeps form the centre about which are grouped the events of a history which is not that alone of Rome, but of the associated provinces. The Medicean manuscript designates the work *Ab Excessu Divi Augusti*, and this is no doubt the original title. In the *Histories* Tacitus writes as a contemporary, and therefore with a surer touch, and he gives full play to his dramatic powers in his description of what is quite familiar to him. The *Annals* represent the culminating task of his lifetime and are the work of the period of his full development as a writer.

The great power of Tacitus as an historian is due to his skill in discerning the motives which lead men to act, and his 'deep psychological insight' is very marked. He studies men, not things, and hence he is skilled in character painting. A marked feature of the Tacitean spirit is the tendency to impute a base or unworthy motive to all the actions of those men whom he describes. This is particularly true of his treatment of Tiberius. Certain it is that Tacitus writes of Roman society as a pessimist, and we may obtain a juster view by turning to the more attractive picture presented by his friend and contemporary Pliny the Younger.

Tacitus early recognized that the style taught in the schools of rhetoric was not adequate for his history, and he thereupon evolved one of his own. There are three distinguishing features of Tacitus's style—conciseness, variety, and poetical coloring. There is not a superfluous word, and his condensation sometimes causes obscurity. We may say that his conciseness corresponds to his thought, for there is nothing artificial in it, and the style is characteristic of the writer. Tacitus's fondness for variety is found in his word positions, and in his variation in forms and constructions. The poetical coloring came from his study of the Augustan poets, particularly Vergil. Many words and expressions may be traced to Vergil, and this is true particularly of the minor writings and the *Histories*.

The manuscripts of Tacitus are the Codex Mediceus (I.), dating from the ninth century and containing a part of the *Annals;* and the Codex Mediceus (II.) of the eleventh or twelfth centuries containing what remains of the other books of the *Annals* and *Histories*. The *Germania* and *Dialogus* are obtained from a manuscript in the Vatican based on an earlier one of the ninth century and again from a manuscript at Leyden, dating from the fifteenth century. The *Agricola* is found in two transcriptions of the fifteenth century now in the Vatican. The *editio princeps* is by Puteolanus of Milan, about 1476. The best text is that of C. Halm in the "Teubner Series" (Leipzig, 1886). Important editions are the *Annals*, with English notes by H. Furneaux (Oxford, 1891-92; vol. i., 2d ed. 1896); Allen, *The Annals of Tacitus*, i.-vi. (Boston, 1890); Nipperdey and Andresen, *Ab Excessu Divi Augusti* (Berlin, 1892); Codley, *The Histories* (New York, 1891); Spooner (London, 1891); Frost, *Agricola* and *Germania* (ib., 1861); Hopkins (Boston, 1893); Furneaux, *The Agricola* (Oxford, 1896); Gudeman (Boston, 1899); id., *Dialogus* (ib., 1894); and Peterson (Oxford, 1893). The lexicons for Tacitus are Boetticher's (1832) and the great work of Gerber and Greef (completed 1903). An excellent English translation is that by Church and Brodribb (London, 1876-77).



TACKING (from *tack*, from OF. *taque, tache*, dialectic Fr. *tache*, nail, tack; so called because of the part of the sail to which the rope is attached) AND **WEARING** (from *wear*, AS. *werian*, Goth. *wasjan*, OHG. *werjan*, to clothe; connected with Lat. *vestis*, Gk. *ἑσθής, esthēs*, clothing, Skt. *vas*, to put on clothing). A vessel is said to be *on the starboard tack* when she is sailing with the wind on her starboard side, and *on the port tack* when the wind is on her port side. She is *close-hauled* on either tack when she is sailing as near to the wind as the set of her sails permits. The operation of changing from one tack to the other is called *tacking* if the vessel comes up head to wind and then falls off on the other tack, and *wearing* or *gybing* if she falls off—bringing the wind astern—and then comes up to the wind on the new tack.

TACKING.

It is evident from the sketches that in tacking there is a gain to windward—if the vessel is a weatherly one and well managed—while in wearing there is a loss, because part of the time the ship is running away from the wind. Therefore, tacking is always preferred when practicable. While all properly built vessels will tack under ordinary conditions of sea and wind, there are times when the sea is very rough and the wind so strong that little sail can be carried; or the wind may be too light to give sufficient headway for tacking; or the vessel may be improperly sparred or ballasted. In these cases *wearing* is necessarily resorted to. In vessels carrying fore-and-aft sails only the operation of

tacking requires little labor, but in square-rigged ships the yards must be swung and the sails adjusted on the new tack. *Wearing* is called *gybing* when the vessel is fore-and-aft rigged and carries a boom mainsail which is not taken in or lowered during the operation. It

WEARING.

is evident that when the wind, in wearing, passes from one side to the other of such a sail it will give a thrust of considerable violence, and this thrust must be carefully watched in small vessels—and in large ones if the wind is strong—or it may cause them to capsize.

Tacking is frequently called *going about*. While the operation is in progress a vessel is *in stays;* if she fails to tack and falls back on the same tack as before, she is said to *miss stays*. A lively, fast-moving vessel, particularly if deeply loaded, will, before losing way, shoot some distance directly up into the wind after it is out of her sails. Advantage is frequently taken of this fact to avoid some slight obstruction, when tacking is undesirable or otherwise unnecessary, and the operation is called making a *half board*. To make a *good board* is to lose nothing to leeward; to make *short boards* is to tack frequently; to make *sternboard* is to go astern.

TACKING OF MORTGAGES. The act, permitted by a doctrine in English equity practice, of one who takes a mortgage or lien on real property subsequent to a second or later mortgage and in ignorance of its existence, to purchase the first mortgage and merges or 'tacks' his security in it. The effect of this is to compel the intermediate incumbrancers to redeem the first mortgage, including the one thus merged with it, before they can enforce their liens. This doctrine has been repudiated in most of the United States.

TACKLE (MDutch, Dutch, LG. *takel;* possibly connected with Goth. *taujan*, to do, or with Goth. *tēkan*, Icel. *taka*, AS. *tacan*, to take, Lat. *tangere*, to touch). A combination of blocks and ropes designed to increase the capacity of the available power to move heavy weights or decrease the time required to move an object with a power capable of moving only at a certain speed. The block consists of a *shell* or frame

containing one or more *sheaves* or pulleys and a *strap* to attach the block to the weight or support. It is evident that in all cases one block of a tackle, or one end of the rope—if there is a

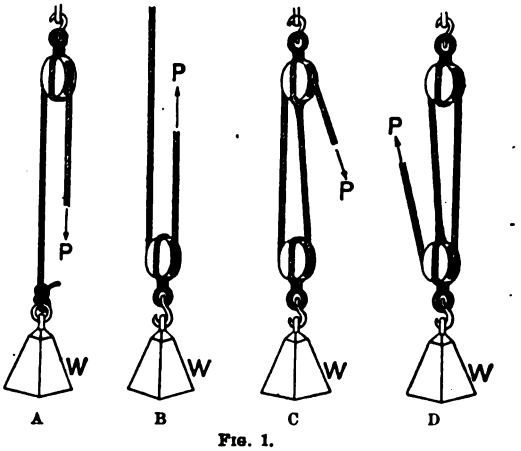


FIG. 1.
A, single whip; B, runner; C and D, gun-tackles.

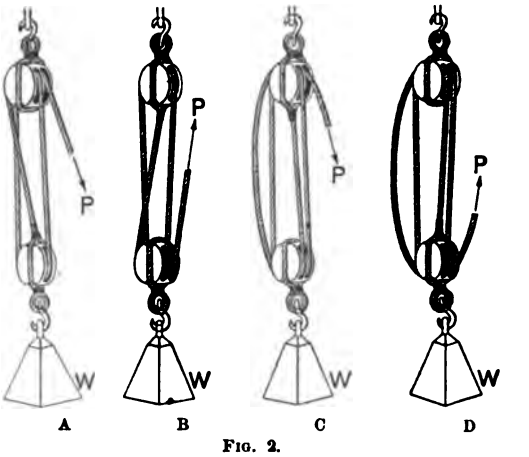

FIG. 2.
A and B, luff or watch tackle; C and D, two-fold purchases.

single movable block—must be fixed. This being the case, in simple purchases and neglecting friction we have $P = \frac{W}{N}$, in which P is the power,

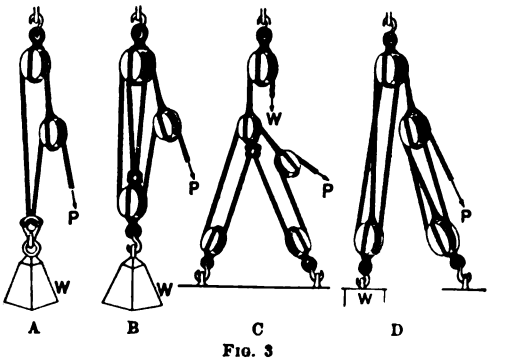

FIG. 3
A, single Spanish burton; B, double Spanish burton; C, Bell's purchase; D, luff upon luff.

W the weight, and N the number of parts of rope at the movable block. The amount of power lost by friction depends upon many things, such as: the character of the rope; its size with reference to the diameter of the pulley and the weight to be raised; the condition of the atmosphere; the bearings of the pulleys, etc. But in ordinary tackles, with the usual type of pulleys, rope, etc., the loss by friction is estimated at about one-sixth the gain effected by each pulley or sheave. The different classes of tackles, or *purchases* as they are frequently called, are shown in the accompanying figures.

TACKLETON, Mr. A toy-maker with a virulent dislike of toys and children, in Dickens's *Cricket on the Hearth.*

TACLOBAN, tä-klō'-bän. Capital of the Province of Leyte (q.v.), Philippine Islands, in latitude 11° 15′ N. and longitude 124° 59′ 30″ E. The town, which is on the eastern coast, is well built and has an important trade. The port is well protected and has four different wharves. Population, about 11,000.

TACNA, täk'nä. The northernmost province of Chile, bounded by Peru on the north, Bolivia on the east, the Chilean Province of Tarapacá on the south, and the Pacific on the west (Map: Bolivia, C 7). Area, 8688 square miles. Its level and arid interior is inclosed by the slopes of the Andes on the east and the coast range on the west. The rainfall is very scanty, and with the exception of the river valleys, the interior is an arid desert. The climate is unhealthful and earthquakes are not infrequent. There are deposits of nitrate, silver, and copper, which are mined to a limited extent. Population, in 1895, 24,160; in 1900 (estimated), 25,031, concentrated chiefly in the capital, Tacna (q.v.), and the port Arica. The province formerly belonged to Peru and was ceded to Chile for a period of ten years in 1884. At the expiration of that period, according to the provisions of the treaty, the ownership of the province was to have been determined by a plebiscite of the inhabitants. The political state of Peru, however, made it impossible to carry out the provisions of the treaty, and Chile still exercises control.

TACNA. The capital of the Province of Tacna, Chile, in the northwestern part of the province, about 40 miles by rail from Arica (Map: Bolivia, C 7). It was formerly a place of considerable commercial importance with notable municipal and industrial establishments, but the construction of railway lines in the Province of Antofagasta diverted the trade southward. Population, in 1895, 9418, as against 14,000 in 1885. In the vicinity a battle took place on May 26, 1880, betwen the Chilean and the allied Peruvian and Bolivian forces, in which the former were victorious.

TACO'MA. The county-seat of Pierce County, Wash., 140 miles north of Portland, Ore., at the head of Commencement Bay, Puget Sound (Map: Washington, C 2). It is a terminus of the Northern Pacific Railway, and is on the Great Northern, the Canadian Pacific, and other railroads. Many steamship lines, of which several are trans-Pacific, sail from Tacoma. The harbor is spacious and secure, and is admirably provided with shipping facilities, the railroad and steamship terminals being among the best on the Pacific Coast.

Tacoma has a picturesque site, rising from the bay to an altitude of 320 feet, with high mountains in the vicinity, Mount Rainier (q.v.), locally known by the old Indian name, Tacoma, to the southeast, being 14,526 feet in height. There are some 700 acres in public parks, of which Point Defiance is by far the largest. The city hall, court-house, Chamber of Commerce, Northern Pacific Railway headquarters, Tacoma Hotel, and Tacoma Theatre are among the prominent buildings. The city has a public library (Carnegie) containing some 25,000 volumes, the Ferry Museum of Art, and the State Historical Society. The educational institutions include Whitworth College (Presbyterian) and the University of Puget Sound (Methodist Episcopal), both opened in 1890; Annie Wright Seminary (Protestant Episcopal), the Pacific Lutheran University, and an Indian school. The State Insane Asylum is a few miles to the south, and there are in the city a number of charitable institutions, the more important of which are the City and County Hospital, Saint Joseph's Hospital, and the Fanny Paddock Memorial Hospital.

Superior transportation facilities, and a vast and highly productive tributary region have made Tacoma one of the leading business centres on the Pacific Coast. Coal is mined extensively in the vicinity, and the city has also advantages of rich agricultural and timber lands. It carries on a large wholesale trade and is largely interested in manufacturing, but derives its chief importance from an extensive coastwise and foreign commerce, particularly with the Orient. The principal articles of commerce are wheat, flour, lumber, coal, coke, fish, and fruit. In the census year 1900 the various industrial establishments had $8,147,000 capital, and an output valued at $12,029,000. The manufacture of lumber, shingles, furniture, carriages and wagons, woodenware, flour, foundry and machine shop products, cars, car wheels, and engines, ship and boat-building, smelting, and brewing are the chief industries.

Under the revised charter of 1896 the government is vested in a mayor, elected for two years, and a unicameral council. Most of the administrative officials are appointed by the mayor, the comptroller, treasurer, and board of education, however, being chosen by popular vote. The city spends annually for maintenance and operation about $698,000, the largest items being: interest on debt, $228.000; schools, $164,000; electric light plant, $69,000; fire department, $47,000; police department, $35,000. The water-works and the electric light plant are owned and operated by the municipality. Tacoma was formed in 1883 by the consolidation of Old Tacoma (founded in 1868) and New Tacoma. New Tacoma, founded about 1869, was made the western terminus of the Northern Pacific Railway in 1873, was organized as a city in 1874, and became the county-seat in 1880. Population, in 1890, 36,006; in 1900, 37,714.

TACOMA, Mount. A peak of the Cascade Range. See Rainier, Mount.

TACONIC MOUNTAINS, or TAGHKANIC MOUNTAINS. A low mountain range on the eastern boundary of New York State and occupy-

ing a small area in Massachusetts and Vermont (Map: Massachusetts, A 3). It extends from the Highlands east of the Hudson in a north-northeast direction, becoming gradually higher as it enters the northwestern corner of Massachusetts, and passes into southwestern Vermont, where it connects with the Green Mountains. Its highest peaks are Mount Equinox in Vermont, 3816 feet, and Greylock in Massachusetts, 3535 feet. It consists chiefly of metamorphosed Cambrian and Silurian rocks to which it has given the name Taconic System (q.v.).

TACONIC SYSTEM. A name applied by Emmons in 1842 to a series of rocks found in eastern New York, western Massachusetts, and Vermont, and considered by him to be of pre-Potsdam age because of their metamorphosed character and the supposed absence of fossils. It has been suggested by some that the term Taconic should be substituted for Cambrian. Consult: Emmons, *Geology of New York*, part ii. (Albany, 1842); Dana, "A Brief History of Taconic Ideas," in *American Journal of Science*, third series, vol. xxxvi. (New Haven).

TACTICS (from Gk. *τακτικός, taktikos*, relating to arrangement, especially in war, from *τακτός, taktos*, arranged, from *τάσσειν, tassein*, to arrange), MILITARY. The art of conducting and arranging troops on the battlefield, or in its immediate vicinity. Strategy (q.v.) strives to make all the conditions for the coming battle favorable, while tactics endeavors to realize what strategy has prepared for. The same principles apply in both, but tactics is more dependent on actual practice, while strategy is more of an art, derived from study, reflection, and genius.

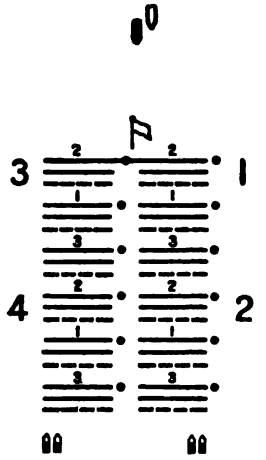
Tactics not only demands from the individual officer understanding, comprehension, and genius, but in addition the masters of the art must be men of iron constitution and iron will. War alone can develop great soldiers—they are born, not made. But even they need preparation, education, and training—not to acquire theoretical knowledge, but to learn how to handle the tools of their art. Moreover, the great leaders need assistants, and these can be developed from the men of average ability, by the careful study of the use of the tools required, and practice with them and by the lessons of military history, bearing in mind that every case arising in war is an exception, and will never arise again, and not a general rule which may be used as a model.

TACTICS OF INFANTRY.

Infantry, except during a single period, namely, the Era of Knights or the Age of Chivalry, has always been the *principal* arm, that is to say numerically the strongest, and in its action the most decisive, and ever since the introduction of firearms the infantry has been gaining in importance. It is the only arm which can act *independently*, that is without the assistance of the other arms, under all conditions of ground, weather, and other circumstances, in attack or defense, while in motion or when at rest, in closed or open order, with fire action or shock action; it can operate on all kinds of ground; it is more independent of circumstances than the other arms; in it movement and effective firing may be combined to a far greater extent than in the other arms; it can come into action more easily and readily; it is equally effective in attack and defense; it is more easily and cheaply equipped and maintained than the other arms; and it can be more quickly made efficient. But it is limited in its rate of movement, hence the advantage of combining cavalry with it; and in the range of its effective action, hence the advantage of combining artillery with it for battle, and cavalry for reconnaissance.

Infantry holds its high position mainly on account of its great fire-action combined with its capacity to utilize fully the configuration of the ground.

The fire of the present breech-loading rifle begins to make itself felt at 2500 yards, but does not become effective as aimed fire until about 1000 yards from the enemy; at 500 yards it is decisive, and at 300 practically annihilating. Constant improvement gradually increases these distances, and in the Boer War it was noticed that the British attack usually came to a standstill at 900 yards.



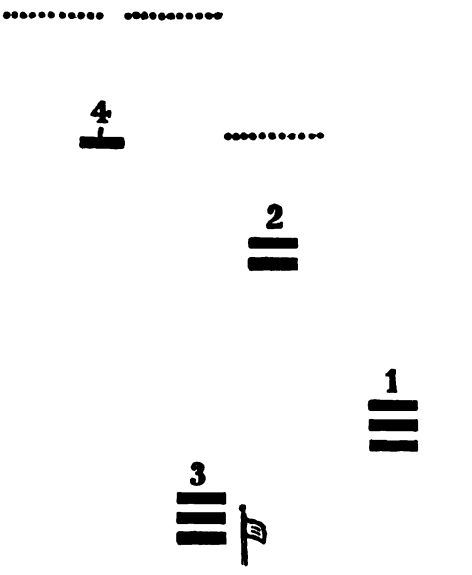
The perfection of firearms and the more extended utilization of the configuration of the ground have greatly increased the power and significance of fire-action. The introduction of an automatic firearm is now only a question of a comparatively short time, and this will still further increase fire effect. The bayonet attack, as an independent act, has ceased to exist; it can no longer overcome fire-action, but can only win the results of previous fire-action. The latter takes by far the longer time and makes the highest demands on the strength and endurance of the troops; moreover, its annihilating effect punishes promptly any rash resort to the bayonet. Nevertheless the necessity for the bayonet remains; not indeed in hand to hand conflict, but as a threatening measure in the assault of a position, and because of the confidence it inspires and the power of the initiative which it confers. According to the great German tactician Meckel, "The laurel of victory still hangs on the point of the bayonet."

The power of infantry fire necessitates cover, and the utilization of the natural configuration of the ground to secure this has acquired vital importance. The crossing of open spaces is avoided as much as possible, or postponed to decisive moments; hence, the battle usually crystallizes around woods, villages, and groups of buildings. But in broad open fields, as in the United States, or where troops are opposed to each other in strong natural or artificial positions for a considerable time, artificial cover must be obtained, consequently intrenchment is resorted to, and an intrenching tool has become a necessary part of the soldier's equipment.

The formations in which infantry moves and fights are not the result of haphazard theory, but have grown out of the conditions of warfare, and their importance is attested by the fact that, in spite of the improvement in firearms, the losses in battle have become gradually smaller. Infantry can fight only when the distance from the enemy, or the available natural or artificial cover, permits it to fire, and effective fire can only be obtained when the soldier has room to use his arm freely, consequently this arm fights in open or dispersed order, the closed order being used only for troops in rear of the firing line. The greatest difficulty in leading infantry is the loss of control by the officers due to this dispersed order, and this can only be overcome by

training, discipline, drill, and the example of the officers.

The tactics of infantry are designed to facilitate, as far as in them lies, that great object of every commander, namely, to make himself stronger than the enemy at the time and place of actual combat, and this can only be done by preserving unity of command, concerted action and mobility, combined with the least exposure of the men to loss. The formations in use attempt to fulfill these conditions, and the main principles governing in modern **infantry tactics are: an individual** training and instruction to develop a high degree of initiative combined with perfect subordination; the greatest development of fire in the firing line; a subdivision into fire units of such strength as to insure complete fire control by commanders; in the attack, pressure against the flank combined with a frontal attack; the reinforcement of the firing line by a succession of lines gradually closing to the front; and, if possible, the accumulation of a greater depth of forces opposite the portions of the enemy where the attack is to be concentrated.



BATTALION DOUBLE COLUMN.

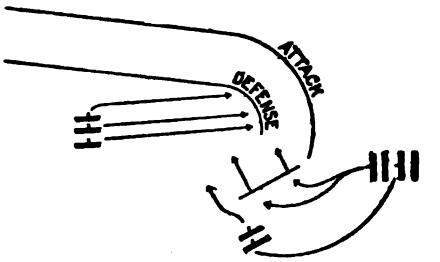
Colors; Battalion Commander; Adjutant; Company Commander; Platoon Commander.

The double column of the battalion (from which the column of march is usually deployed for battle). The larger numbers indicate the companies, the smaller the platoons.

The front line in the attack is composed of the *fighting line* and its *reserve*, and the former is subdivided into the actual *firing line* and its *supports*. The battalion is the tactical unit and the front it covers, as well as the particular nature of the action, determines the number of companies it places in the fighting line. The battalion covers normally about 400 yards of front and a company about 100 yards. The progress of the attack will proceed in general outline somewhat as follows: Before entering the zone of artillery fire (or at about 3000 yards) each regiment forms from column of march into line; the battalions then designate the companies to form the fighting line and those to form the reserve; the companies of the fighting line then designate the sections for the firing line and for the supports. The best form of advance of the companies is in column of sections (half platoons). This line of columns is kept up as long as possible, because in this formation the men are under the perfect control of their officers. Within effective infantry fire the column must deploy, since the bullet from the modern firearm can pass through two men at 1500 yards, and at 400 yards it can go through four men, so that the column, if preserved here, must expect heavy losses. In the attack closed columns cannot appear in open country within a range of 2100 yards. The successive lines, deployed in open order, or in company column of sections, depend-

A BATTALION ON THE RIGHT FLANK OF A GENERAL LINE DEPLOYED FOR BATTLE.

On a war footing the companies have three platoons each. The numbers indicate the companies, the fourth having two platoons deployed.



ing on the effect of the enemy's fire, continue to advance. When within effective range, fire is opened, by volleys, or a designated number of rounds at will, the skirmishers halting to deliver their fire, then advancing again. In open country, within 1100 yards skirmishers can no longer remain standing. The supports gradually close on the firing line, deploy as skirmishers and begin to reënforce the firing line. Then begins the advance by rushes, by alternate subdivisions, and portions of the reserve are added to the firing line, the rest still held in reserve in rear of the point of main attack. The final act is the charge, the reserves being brought up to insure victory and hold the position. The engagement is in general decided at about 900 yards' distance.

This is the general picture, but the details are very various. Long lines of skirmishers can only advance or retire on lines perpendicular to the front, and changes of front are no longer possible after the open order is adopted; moreover, throwing out a skirmish line oblique to the front is dangerous, consequently the companies must first be placed on the front to be formed before deploying as skirmishers. The skirmish line, to avoid losses, is often compelled to advance at a run, and systematic rushes are possible only on the drill ground; in the field these rapid advances depend on the local conditions, especially the effect of the enemy's fire. The long line, at three or four thousand yards from the enemy, will pass over varied ground, part covered, part open; on the latter artillery fire will make itself felt here and there, and at such points the men will advance at a run, then halt under cover, or out of the zone of fire, to await the other parts of the

line. These conditions will constantly change in all the different parts of the field.

The infantry attack is decided by fire-action, and to determine the number of skirmishers in the firing line, it must be remembered that there should be at least enough to prevent surprises, and not so many as to interfere with the commander's freedom of action, in case, for example, it should turn out that a considerable portion of the forces had been placed where they were not really needed. The further development of the fire-action will be determined by the points selected for decisive action, which cannot usually be determined beforehand.

One of the principal conditions for the success of the attack is that fire once opened should be kept up to about the same strength, and this again indicates the necessity for comparatively weak lines at first; on the other hand, the enemy should be met with superior forces from the beginning, and this superiority kept up. Between these two limits the commander must decide.

THE FLANK ATTACK.

The attack covers the entire front of the defense and has in addition sufficient troops for outflanking the right wing of the latter, and attacking him in a direction perpendicular to his front.

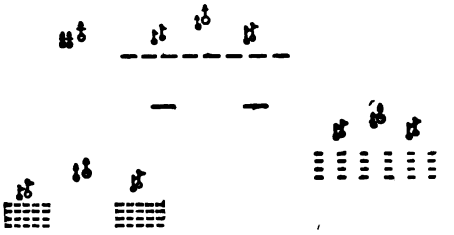
Decisive action is usually sought on a flank, but not necessarily an extreme outer flank of the line, for a modern skirmish line, from various causes, is very apt to have a number of inner flanks, which are also points of weakness. In the early part of the engagement the enemy must be forced to unveil his position, and then these interior flanks can be determined, and the commander may decide where to concentrate his forces, for superiority is desired only at the decisive points. The rest of the front can be held by comparatively weak forces. This also indicates the necessity for keeping as many troops as possible in reserve, but it must be borne in mind that the requisite number to insure superiority must be put in the firing line from the beginning, and this aside from all other considerations. The reserves must be added to the firing line in dispersed order, for the commander who hopes to force a decisive action by means of reserves in closed order disregards the effects of modern firearms. In an ideal action all the rifles are in use at the decisive moment, but this is not possible in long lines. Still, the troops remaining in close formation will find other uses. To cover a retiring skirmish line only those reserves can be used that stand far enough to the rear to be readily placed in a defensive position to which the line may fall back; if they are already on the way to the front they had better be thrown into the skirmish line, to turn the tide, if possible.

Breaking through the front of a line is a very difficult undertaking and hardly possible to-day. Consequently, the reserves should not be in rear of the centre, because they are of no use there, and would have to be kept so far in rear, to avoid the effects of the enemy's fire, that they might not enter the action in time. Their place is on one or both flanks, and so far beyond the flanks that they can enter the fight by a simple, direct forward movement, without any lateral gaining of ground. A regiment held in reserve, for example, should be placed in rear of the flank and about 600 yards beyond it. The main reserve is always behind the flank where the decisive action is expected to be brought about.

The regimental commander can only assign to each battalion its general duty; the execution must be left to the battalion commanders. On the defensive he assigns to each his section of ground, on the offensive his point of attack; and he lets go his control as fast as the circumstances require. The battalion commander, in the same way, gradually gives up control of his companies, and when once the battalion is deployed, he can only aid by caring for the supply of ammunition. A skirmish line fires only when at a halt, and the position taken depends on the range, but lying prone is now regarded as best because it gives the enemy's artillery no opportunity to get the range. Before opening fire the distance must be estimated, a difficult matter even for those well trained in it in time of peace. The skillful designation of the target also requires much practice. The firing may be by volley or at will, the former being advantageous when the range has been determined and the ground is suitable for observation of the fire, but in general is merely a drill-ground exercise of little practical use. The conduct of the fire and all fire control is in the hands of the company and subordinate commanders, and one of the most difficult duties of these officers is the observation of the effects of the fire.

These are the generally accepted principles of infantry tactics, but in the different States of Europe there are still considerable variations. The fighting front of a battalion, for example, varies from 200 yards in the Italian Army to 400 in the French, and the latter has practically abolished the supports for the firing line. In France and Russia fire is opened at great ranges, over 1900 yards; all the nations except Germany lay great stress on volley firing. Again, in France (and in the United States, as set forth in Wagner's *Tactics and Organization*, New York, 1895, officially approved), great attention is given to successive regular lines of attack, the first to introduce the action, the second to carry it out, and the third as a reserve: an indication of a love for theoretical forms, types, and systems in matters that are too elusive for such treatment, and which experience on the battlefield has shown to be very different in practice.

TACTICS OF CAVALRY.



The prominent characteristic of cavalry is *rapidity* of movement, and its greatest duty is the service of security and information: a cavalry which is superior to the enemy's in screening its own army and clearing up that of its adversary will more than pay for itself. Its duty next in importance is pursuit, as it alone is capable

of overtaking and holding a retreating enemy till the arrival of the infantry. On the battlefield its use is important, but limited.

Cavalry is the arm of surprise, of sudden and vigorous attack; but its power of defense is comparatively poor, consequently it cannot hold for any length of time the ground it has gained. It is dependent to a great extent on the configuration and character of the ground, and its use in conjunction with the other arms is limited to favorable moments. Cavalry for its best and most effective action requires a broad, open country, and this is available only rarely on modern battlefields. For this reason, and on account of the increased range, rapidity of fire, and accuracy of firearms, cavalry can seldom decide battles.

Surprise is to-day absolutely essential for the success of a cavalry attack, but to seize the proper moment is very difficult, and requires constant watching of the progress of the battle, and even anticipation of the enemy's movements in order to place the cavalry in readiness to grasp the fleeting moment, ere it be too late; consequently the cavalry must often wait for hours, and even under fire, but of course this has its limits, and after a certain percentage of losses the cavalry must retire out of range, and thus give up temporarily any opportunities for attack that may possibly arise.

The true action of cavalry in battle has been shock action, its fire-action being quite subordinate, and employed mainly on the defensive. Under present conditions the precise sphere of activity for the arm in battle is a subject of much debate. Positions seized by an advancing cavalry may sometimes be held by its means until the infantry comes up, or it may be used to check the advance of the enemy; occasionally it may serve to support infantry. As a rule, fire-action of cavalry is delivered dismounted, but mounted fire-action, although rare, has been used with advantage in covering a retreat when the pursuit was very active. The formation of

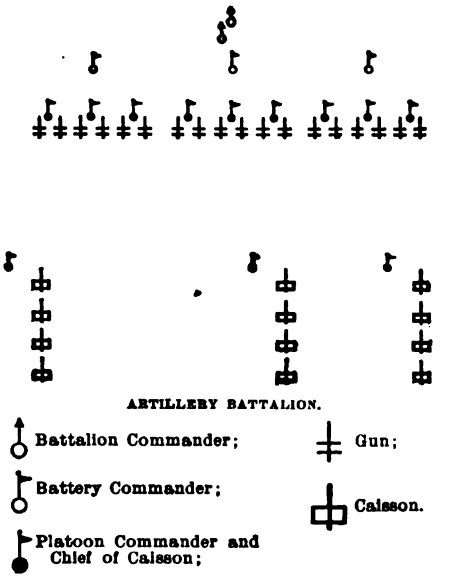
CAVALRY DIVISION DEPLOYED.

Division Commander; Regiment Commander; Battalion Commander;
Division Staff Officers; Regiment Adjutant; Battalion Adjutant.

The division represented is composed of three regiments, one of which is deployed in line; the regiment on the right flank is in line of squadrons in column of troops with extended intervals ready to deploy; the other regiment is massed in close column.

cavalry used in the attack is the line, composed of two ranks in Europe. At other times the cavalry is generally kept in columns. The line allows of the simultaneous use of the greatest number of weapons, but because of its unwieldiness the squadron front is not exceeded for any formations other than the attack. Columns serve to assemble the troops in a narrow space, and render movement up to the moment of attack easy; they must be open to facilitate forming line, with comparatively narrow front and full distances.

In the attack of *cavalry against cavalry*, victory can be gained only by the rapid assault of closed lines. In the advance of two opposed lines toward each other the respective lines will necessarily be more or less broken, the closed portions of the line still remaining on either side will penetrate the open places, both fronts will thus be broken through, and a hand to hand conflict begins. The extent to which either side retains closed lines up to the last will be of great effect on the result, hence the necessity of keeping closed and advancing with determination. The squadron commander can always take personal part in the attack, and the regimental commander can generally do so, but the brigade commander very rarely. The enemy should be kept uncertain as to the direction of the proposed attack as long as possible, so that he cannot prepare to meet the attack on his flank or rear, where it is usually directed. The principles applying to the subdivision of the forces are the same as for infantry. Enough men must be put into action at the beginning to insure success, and the first contact should decide the affair, consequently the forces directed against the flanks must be so directed from the beginning, and therefore must have an entirely different base from those directed against the front. In the front it will hardly be possible to put more men than the enemy has, and overlapping flanks will charge against nothing. More than necessary for decisive action should not be put in at first, because a reserve will be necessary to meet other approaching troops while the attack is going on. However, if all the troops are needed for the first effect then there can be no reserve, but one should be formed as soon as possible out of the reassembled squadrons. After the attack the action gradually changes into flight on one side and pursuit on the other, and the latter should be kept up till new infantry or artillery stops it, or the horses are exhausted.



In the attack of *cavalry against infantry* victory can only result when the attack is so sudden that the infantry has no time to fire at all, or when the latter is badly demoralized by previous losses. *Cavalry against artillery* has a better chance for success, because a firing artillery line cannot protect itself toward the flanks, and in the early part of an engagement such unprotected lines will often be found. *Fighting on foot* enables cavalry to act for a time independently of the other arms, especially when it is supported by horse artillery, and is the only means by which cavalry can continue its advance through defiles, woods, or villages occupied by weak forces of the enemy. The action of dismounted cavalry is limited in general to holding particular points, such as defiles or villages, until the arrival of stronger forces. There are, however, instances where cavalry on account of their extreme mobility can be used advantageously in foot fighting, and modern tacticians are paying increased attention to this point. Such cavalry, however, must be distinguished from mere mounted infantry as they have a far wider tactical use.

The principal duty of the horse artillery attached to the cavalry is to support the latter, since it can clear out the enemy from positions which a cavalry force would have hard work to take. In the attack of cavalry against cavalry horse artillery cannot always find application, but it can aid when its cavalry is deploying from a defile. While the opposed cavalries are still manœuvring the artillery takes the enemy's cavalry as its target, and pays no attention to its artillery unless its fire is masked by its own cavalry or to facilitate the deployment of its own cavalry. The artillery should be massed, but artillery duels to prepare the action would be absurd. There will probably be no time for any change of position until after the cavalry attack is decided, when the artillery takes part in the pursuit. In case of defeat it will not have time to take up a new position, but must remain firing in its previous position.

These are in outline the principles involved in cavalry tactics, though they are constantly undergoing modifications and the discussion of the true sphere and use of cavalry is a favorite topic for military authorities. In France more attention is given to theoretical forms, and the French tactics prescribe three lines for the division, the third being a reserve in the hands of the division commander, which is put into action only by squadrons and never entirely, except as a last resort; and the horse batteries are directed to form about 900 yards on the flank of the field of attack.

TACTICS OF FIELD ARTILLERY.

The artillery is the arm of destruction, and, on account of its great moral effect and the fact that it can reach troops in every part of the field, in all kinds of ground, and behind all artificial field cover, it is essentially the arm for preparing for the attack, demoralizing the enemy, and facilitating the work of the other arms. The use of artillery in masses is the great feature of a modern battle, and this use results from the long range of the guns, which enables them to do in one position that which formerly required a number. Its mass action begins the battle, prepares it, supports the action of the other arms, and ends it, and as an arm of pursuit artillery ranks with cavalry. The disadvantages of artillery are that it is tied for a considerable period to a particular position, and cannot act alone, consequently it is always an auxiliary arm. Moreover, it is cumbersome in its movement and defenseless when moving. It is also expensive and difficult to train. Leaving out of consideration the artillery of the seacoast and that used in the attack and defense of land fortifications, which have a tactics of their own, that is treated elsewhere (see COAST DEFENSE and FORTIFICATIONS, ATTACK AND DEFENSE OF), the artillery taken along by the field army may be divided into light artillery and heavy artillery, the former comprising field, horse, and mountain batteries, the latter guns of position. The field batteries include howitzer and mortar batteries for curved or high-angle fire. The formations of the artillery of practical use in the field are simply a formation for going into battery, and the formation *in battery*, ready for firing. To train the cannoneer for his arduous work under enormous strain, the greatest precision in accuracy in drill must be insisted upon, for the numerous duties of a cannoneer (setting the fuze accurately, also the sight for the range as well as deviation ordered, and the use of the trail in pointing), under a fire, which may burst shells near the battery as often as one a second from each of the enemy's batteries, require the highest order of discipline. Moreover, to regulate the fire properly, each shot must be observed, in order to correct fuze-setting and sight. All this demands a formation of the battery in a small space, so that the men may be directly under the eyes of their superiors, and the batteries must be able to move easily, under cover if possible, to their positions. Beyond the range of firearms the artillery can move in column of platoons, but within that zone it apears only in the open order (in line at full intervals) or in column of sections. Firing artillery always stands in the open order (*in battery*), and this formation in open order is also the best for advancing into position, where it can be used, but the column of sections will be more generally applicable in coming into position.

This illustrates the manner in which an artillery battalion of three batteries (of six pieces and four caissons each) comes into action. The rest of the caissons are concealed further to the rear.

The greater range of artillery naturally makes it the arm to open the battle, and the desire to rapidly overpower the enemy's artillery, in order that it may take under fire the point selected for attack by the infantry, or, on the defensive, the enemy's infantry during the attack (the real duty of the artillery), as naturally leads to the accumulation of the artillery in masses. The support of the infantry attack is the true purpose and the real duty of the artillery, and everything else is only a means to this end. Consequently, the object which the commander-in-chief has in view determines the time, place, and strength in which the artillery is first placed in position, and he also must give the orders therefor. The artillery should, of course, endeavor to utilize its long range, and if possible come into position beyond the range of the enemy's infantry fire, but since its main duty

is to support the infantry, then, in order to give the latter prompt and effective aid, it must not hesitate to enter the zone of infantry fire, if required, because only when the *infantry* is beaten is the battle lost. On the other hand, it is the duty of the neighboring troops of other arms to protect the artillery against infantry fire. This does not, however, relieve the artillery from the duty of reconnoitring the ground, especially on the flanks, and artillery scouts or patrols (under energetic officers or non-commissioned officers) have become a necessity on the battlefield. The artillery, once in position, remains there, the losses being made good from the reserve, the ammunition train, and finally the drivers, while ammunition when exhausted can only be awaited. The battery is never relieved, but constantly strengthened and supported from the rear. Before occupying a position the ground must be carefully reconnoitred, and in selecting positions the principal condition is effective action, hence the target should be plainly visible; but more than that, a clear field of view is desirable because other targets may appear from time to time. This indicates that a line of heights is most suitable. Of course, in many cases some of the batteries will not be able to see the target, and when the enemy's artillery is superior a hidden position may be preferred; in these cases indirect fire must be used, but the problem of overpowering the enemy's artillery is thereby rendered very difficult. As to the distance from the enemy, it can only be stated "as near as possible," remembering that beyond 3200 yards shrapnel is not always effective, and observation of fire extremely difficult; moreover, the enemy's fire determines the inferior limit of a position. Nevertheless, *effect* is more important than *cover;* consequently, if artillery finds that its fire from a good covered position is not effective, it must enter the danger zone. The great masses accumulated on battlefields to-day limit the choice of position very much, and in most cases the problem will be less the selection of a position than making the best use of a given position.

The brigade commander rides over the ground, considers the available space, and with due regard to the targets to be taken under fire, decides what front will be occupied. The regimental and battalion commanders are then given their orders, and the latter indicate to the batteries their respective positions. The batteries then enter their position, keeping the roads as long as possible, and after that utilizing cover when practicable. On a line of heights the guns are placed in position close behind the crest, then moved up so that a man standing can just see the target. No battery opens fire until its guns are ready. In large masses it may be necessary to take up first a preparatory position under cover, so that, moved to the front, the batteries may open fire simultaneously, but this is rarely practicable. The direction of the fire is so arranged that brigade and regimental commanders merely indicate the target in general, while battalion commanders designate the special target for each battery and also decide on a change of targets; the ranging, selection of kind of firing, and the actual firing is left to the battery commanders. Changes of position are, in general, ordered only by the commander-in-chief, but in special cases the artillery must act on its own responsibility. In large masses this change of position takes place by echelons, portions of the line remaining in position and continuing the fire while others advance to the new position.

The attack of the infantry must be supported by the artillery in such wise that the former may overcome the enemy's infantry, consequently the artillery of the attack should be superior to the enemy's from the very first. This does not mean necessarily in numbers, because a smaller force by greater rapidity of movement into position and subsequent ranging may gain the upper hand of a large force. If a weaker artillery fears being overpowered it can await in a preparatory position the arrival of reinforcements, but this will not always be possible, because the circumstances may demand its coming into action at once. In this case the artillery endeavors to utilize the ground to the best advantage. In the attack on a prepared defensive front the entire artillery must be in position before opening fire. By superiority of fire is not meant the complete silencing of the enemy's artillery, but such an effect that, after the artillery duel, which first takes place, the enemy's artillery is no longer able to direct a destructive fire on the attacking infantry. As soon as the attacking infantry approaches too near the enemy the artillery must direct its fire on the ground beyond the objective, to prevent the advance of subdivisions from the rear. The principal duty of the artillery of the defense is to take the attacking infantry, even though it may have overcome by its fire the infantry of the defense, under such a hail of shrapnel as to cause its attack to break down. But in the beginning it will have to take up the artillery duel, and here it has the advantage of selecting and strengthening its positions. It will not do, however, to occupy its positions at the beginning, because if it should be forced to change it will lose all its advantages. Consequently, it takes up at first a preparatory position, until the direction of the attack becomes known, and this has the additional advantage of preventing the attacker from getting an insight into the defender's plans before the battle opens. The artillery of the defense, however, cannot devote all its attention to the attacker's artillery. Wherever the infantry of the attacker gains a strong foothold it must be taken under fire. As soon as the attacking infantry prepares for the final assault the entire situation changes, and the defender's artillery takes up its true rôle. The main effort is directed against the enemy's infantry, and his artillery is only kept occupied by a few guns. During the artillery duel the guns of the defense were kept under cover; now they must come out for their proper work. If the artillery of the defense is overpowered it may retire to be placed in position again during the infantry assault, but this will rarely be possible or effective. It is better to keep it in position, the men lying down for better protection, entering into action again at the decisive moment. Should the enemy's attack be successful, the batteries of the defense remain in position firing to the last, for the loss of the guns is no longer a disgrace on the battlefield, provided the situation demands it.

Every army will hereafter take into the field *batteries of position*, heavy batteries, for breaking down obstacles which the ordinary field ar-

TACTICS, NAVAL. The science of arranging combinations, groupings, movements, and methods of handling of ships and other naval weapons, and the art of carrying these plans into effect. Roughly speaking, tactics may be said to solve the question 'how' a certain operation may be performed; strategy to furnish the reason 'why' it is likely to be desirable. They are necessarily mutually dependent; tactics only provides for effecting conditions found desirable by strategy; and strategy is confined to operations which are tactically practicable. In its broad sense naval tactics includes the manipulation of all naval weapons—the movements of a ship or of a fleet, the methods of mounting and placing guns and of handling them, the placing of torpedo tubes and their handling, etc. In a narrower and more usual sense it is understood to mean the handling of a ship and her weapons or of several ships, leaving the tactics of the gun *per se* to be included in *gunnery*, and those of the torpedo to be studied under *torpedo tactics*.

Of the abstract principles of strategy the most important is to oppose to the enemy at the point of contact a superior force. This may mean more powerful ships, numerical superiority, or a better arrangement for attack and receiving attack. The first point must be secured by superior design; the vessel's guns must be more powerful, better mounted, better protected, or she must carry more of them; or her protection or speed must be superior. Numerical superiority where the opposing ships are equal in number and supposedly equal in power may be attained only by good manœuvring and is likely to be only temporary; but a clever tactician and strategist would be likely to reproduce the inequality whenever opportunity offered. The best disposition of the fleet for attacking and receiving attack must depend upon many circumstances; advantage should be taken of the strong points of your own vessels and the weaknesses of the enemy's. For instance, the better protected ships should seek close action, the others avoid it; ships having heavy bow and stern fire should seek action compelling bow and stern fighting if the enemy is particularly weak in bow and stern guns but relatively strong in broadside fire, etc.

The battle tactics of to-day resemble more nearly those of the galley period than those of the epoch of sail, because steam, like manual power, enables any sort of combination of ships to be made and kept with reasonable precision. And the development of signaling has added to the facility of effecting these combinations, though the most experienced naval officers believe that after a fleet action has begun the changes of formation should be simple and few in number.

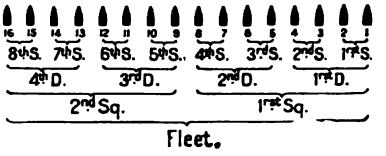


FIG. 1. FLEET IN LINE, NATURAL ORDER.
Showing numbers of section (S), division (D), and squadron (Sq.).

There are three principal formations, *line* (Fig. 1), *column* (Fig. 2), and *echelon* (Fig. 3). In England line is frequently called 'line abreast' and column styled 'line ahead.' In Figs. 1 and 2 a fleet of 16 ships is shown divided into two

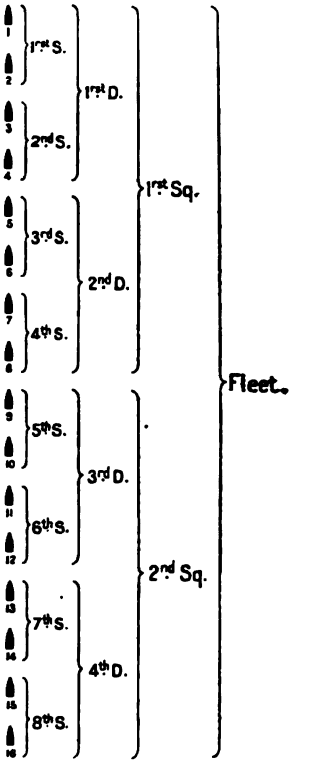

FIG. 2. FLEET IN COLUMN, NATURAL ORDER.
Showing numbers of sections (S), divisions (D), and squadrons (Sq.).

squadrons of eight ships each. If the fleet consisted of 12 ships it might be divided into three squadrons of four ships each, or two squadrons of six. In the various navies of the world the subdivisions of a fleet are different. Some have

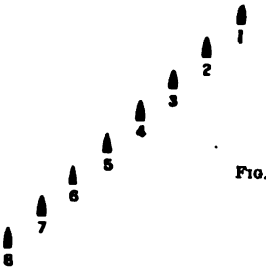

FIG. 3. SQUADRON IN ECHELON, NATURAL ORDER.

units of two, others of three. In the United States Navy a *fleet* consists of two or more *squadrons;* a *squadron*, of two to eight ships; a *division* is half of a squadron which consists of more than five ships; a *section* is a pair of ships

FIG. 4. SQUADRON IN INDENTED LINE, NATURAL ORDER.

forming part of a division or squadron. Vessels, sections, divisions, and squadrons are numbered from van to rear when in column and from right to left when in line. When vessel No. 1 is lead-

ing in column or is on the right when in line the fleet is said to be in *natural order;* if vessel No. 16 is leading or on the right the fleet is said to be in *inverted order.* Vessels not intended for the line of battle are separately formed and manœuvred and constitute the reserve and auxiliary

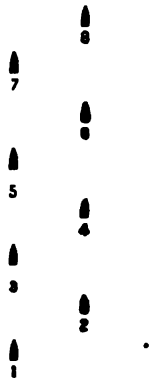

FIG. 5. SQUADRON IN INDENTED COLUMN, INVERTED ORDER.

squadrons, according to their character or the circumstances of the case. Vessels which have a distinct fighting value but are not fast enough or powerful enough to join the fighting line would form the reserve; supply ships, colliers, repair

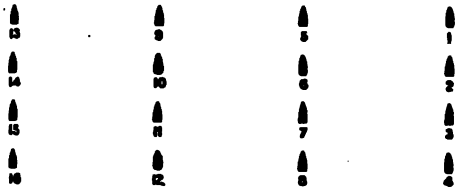

FIG. 6. FLEET IN LINE OF DIVISION COLUMNS, NATURAL ORDER.

ships, etc., would form the auxiliary squadron. The following terms are used:

About. A change of course of 180 degrees. *Advance.* Distance gained to the front in turning. *Alignment.* The direction of the line. *Arc of train or fire.* The angle through which guns may be trained or fired. *Column.* A formation in which vessels are in a line which is in the direction in which they are steering. *Double column* is a similar formation except that there are

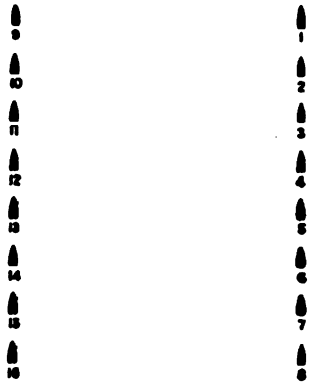

FIG. 7. FLEET IN DOUBLE COLUMN AT SQUADRON DISTANCE, OR LINE OF DOUBLE COLUMN.

two parallel lines. In *indented column* the even-numbered ships are moved slightly to one side instead of being directly in rear of the odd-num-

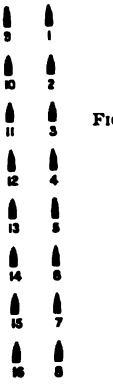

FIG. 8. FLEET IN CLOSE DOUBLE COLUMN.

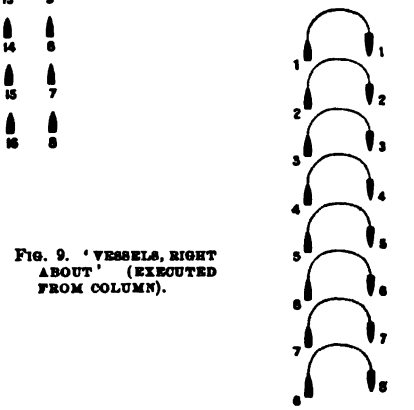

FIG. 9. 'VESSELS, RIGHT ABOUT' (EXECUTED FROM COLUMN).

bered ones. *Distance.* The linear distance (in yards) between the centres or foremasts of ships when in ordinary formation. *Half distance* is

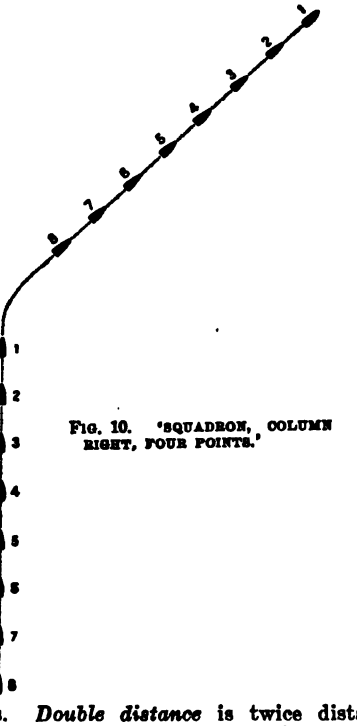

FIG. 10. 'SQUADRON, COLUMN RIGHT, FOUR POINTS.'

half this. *Double distance* is twice distance. *Echelon.* A formation in which the line of bearing of the ships makes an angle of about 45 de-

grees with the direction in which they are steering as in Fig. 3. *Evolution.* The combination of movements by which a fleet is changed from one formation to another. *Flank.* The sea to the

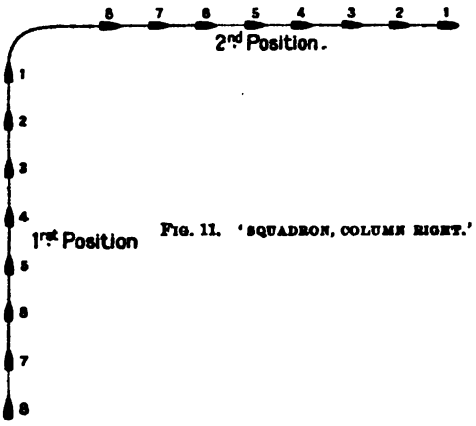

FIG. 11. 'SQUADRON, COLUMN RIGHT.'

right of the fleet is called the right flank; that to the left is called the left flank. *Formation.* The particular arrangement of the fleet. Simple formations are column, line,

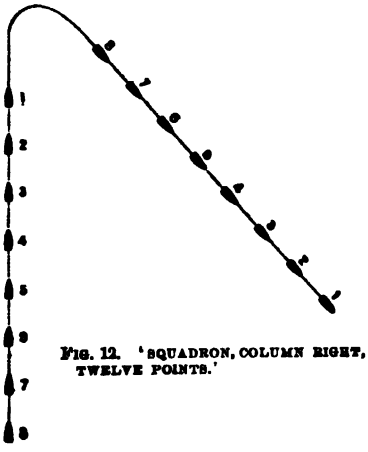

FIG. 12. 'SQUADRON, COLUMN RIGHT, TWELVE POINTS.'

echelon, etc. Compound formations are double column, line of division columns, etc. *Front.* The direction in which the fleet is steaming except when obliquing. The battle front is the

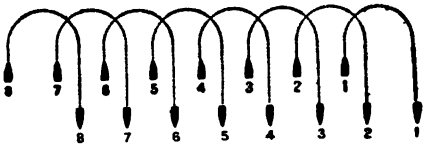

FIG. 13. 'VESSELS, RIGHT ABOUT' (EXECUTED FROM LINE).

direction of the enemy. *Guide.* The ship designated as the one upon which the formation is arranged for alignment and distance. *Interval.* The distance between divisions or squadrons when in compound formation. *Line.* A formation in which the line of bearing of the ships is at right angles to the direction in which they are steaming. *Line of bearing.* An imaginary line passsing through the centres or foremasts of ships when in a particular formation. In compound formations each part has its own line of bearing. *Movement.* One of the component

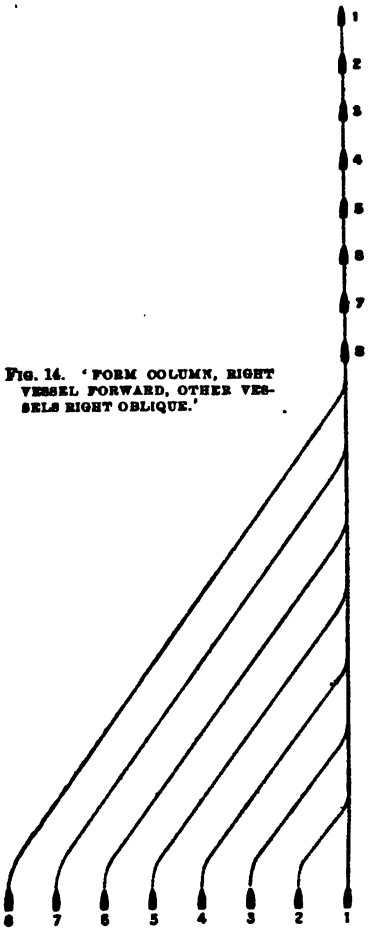

FIG. 14. 'FORM COLUMN, RIGHT VESSEL FORWARD, OTHER VESSELS RIGHT OBLIQUE.'

parts of an evolution. A movement is *simultaneous* when all ships execute it together, and *successive* when executed by each ship or group

FIG. 15. 'SQUADRON, COUNTER-MARCH.'

of ships in turn. *Oblique.* A change of course of less than 90 degrees. The ordinary oblique is three or four points. *Order.* The arrangement

of the fleet (see preceding pages). *Point.* One thirty-second of a circle or 11¼ degrees. *Rear.* The direction opposite to the front. *Speed. Standard* or *battle speed* is that designated for battle or

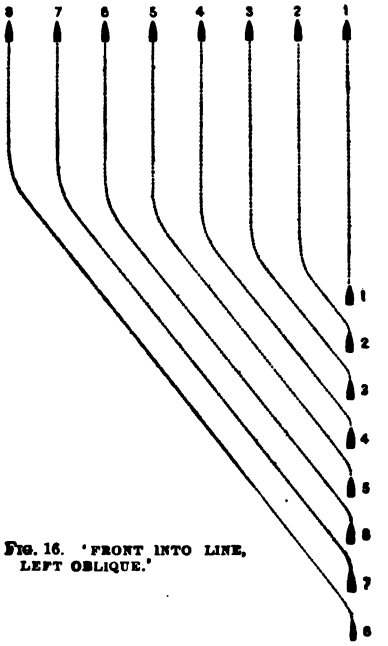

FIG. 16. 'FRONT INTO LINE, LEFT OBLIQUE.'

manœuvres. *Full speed* is a designated speed greater than standard; *half speed* is a designated speed less than standard; and *slow speed* is still less. *Tactical diameter.* The perpen-

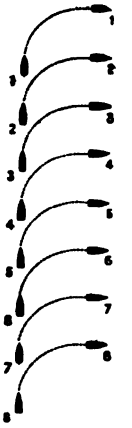

FIG. 17. 'VESSELS, RIGHT TURN.'
The manœuvre changes column to line in this instance.

dicular distance between the course at the beginning of a turn of 180 degrees and the course after the completion of the turn. *Transfer.* Dis-

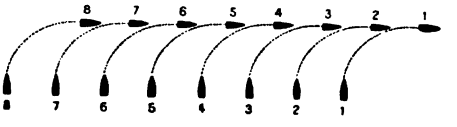

FIG. 18. 'VESSELS, RIGHT TURN.'
In this manœuvre line is changed to column.

tance gained to the right or left (i.e. toward the flank) in turning. *Turn.* A *turn* is a change of course of 90 degrees; a *half turn* is a change of 45 degrees. *Van.* The leading unit of a formation. *Wheel.* A movement in line in which the

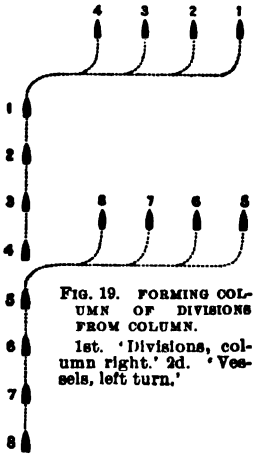

FIG. 19. FORMING COLUMN OF DIVISIONS FROM COLUMN.
1st. 'Divisions, column right.' 2d. 'Vessels, left turn.'

vessels preserve their relative positions but the line of bearing is revolved.

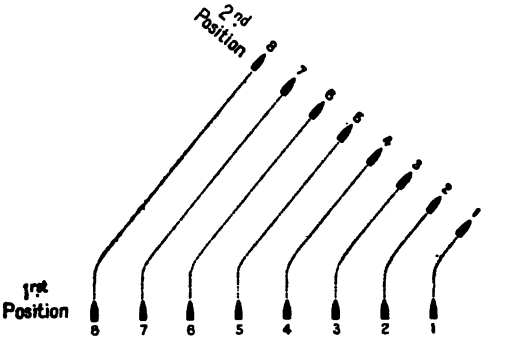

FIG. 20. 'SQUADRON, RIGHT WHEEL, FOUR POINTS.'
Executed similarly for any given number of points.

In performing evolutions there are two principal methods, by *rectangular movements* and by

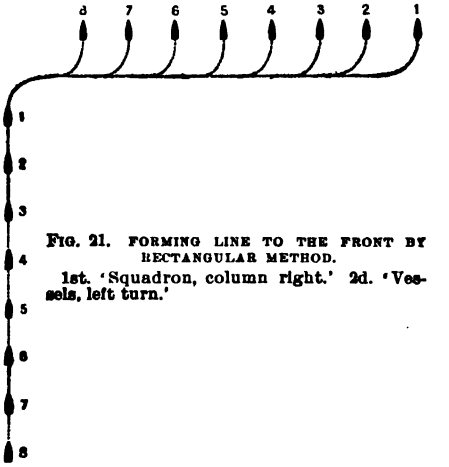

FIG. 21. FORMING LINE TO THE FRONT BY RECTANGULAR METHOD.
1st. 'Squadron, column right.' 2d. 'Vessels, left turn.'

direct or *oblique movements.* Certain evolutions also admit of movement by *isodrome* and others by *conversion* or *wheel.* The ease of movement

attainable with bodies of men is not possible with ships. There can be no turning with fixed pivots, because ships must continue in motion or they cannot be kept under control; nor are sudden halts possible, for a heavy ship moving at high speed cannot be stopped in a less distance than several times her length. These and other considerations have led to the general acceptance of certain rules.

First.—Movements during battle should be as simple as possible.

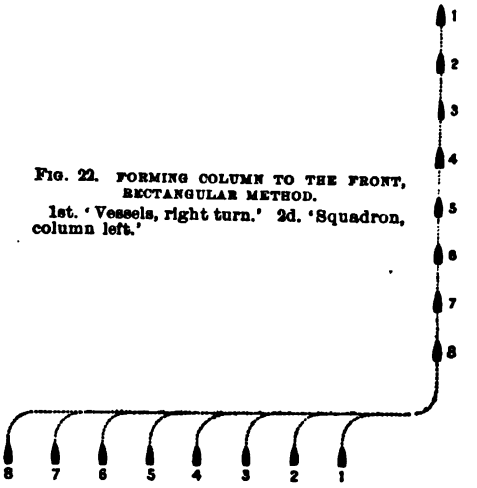

FIG. 22. FORMING COLUMN TO THE FRONT, RECTANGULAR METHOD.
1st. 'Vessels, right turn.' 2d. 'Squadron, column left.'

Second.—Changes in speed, particularly during evolutions, should be avoided as far as possible.

Third.—Evolutions should be performed by the method which requires the least time and the least space.

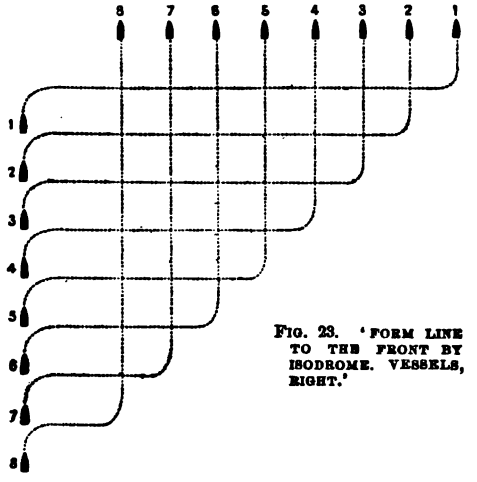

FIG. 23. 'FORM LINE TO THE FRONT BY ISODROME. VESSELS, RIGHT.'

Fourth.—Ships of like characteristics should be separately grouped as far as possible; this is particularly true as regards speed and hardly less so as regards power and arrangement of battery and armor.

Fifth.—When approaching the enemy and until in position to deliver attack the fleet must be kept concentrated and in condition to assume any desired formation.

The accompanying figures show the various formations commonly used and the method of passing from one to the other. With the exceptions of Figs. 1, 2, 6, and 7, the plans show the movements of a squadron of eight ships; the evolutions would be similar for a fleet of sixteen ships.

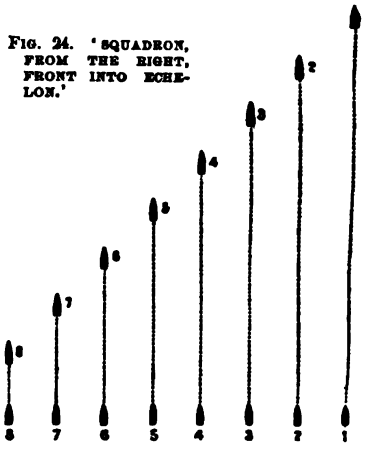

FIG. 24. 'SQUADRON, FROM THE RIGHT, FRONT INTO ECHELON.'

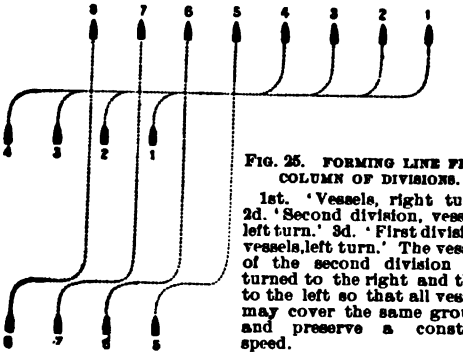

FIG. 25. FORMING LINE FROM COLUMN OF DIVISIONS.
1st. 'Vessels, right turn.' 2d. 'Second division, vessels, left turn.' 3d. 'First division, vessels, left turn.' The vessels of the second division are turned to the right and then to the left so that all vessels may cover the same ground and preserve a constant speed.

BIBLIOGRAPHY. For further information in regard to naval tactics and strategy, see: Captain W. B. Hoff, U. S. N., *Examples, Conclusions, and Maxims of Modern Naval Tactics* (Washington, 1884); Captain F. A. Parker, U. S. N., *Steam Fleet Tactics* (New York, 1863); Admiral Sir G. Elliot, R. N., *A Treatise on Future Naval Battles, etc.* (London, 1885); Saint Farret, French Navy, *Etudes comparatives de tactique navale* (Paris, 1883); also numerous articles in the *Proceedings of the United States Naval Institute*, and in the *Proceedings of the Royal United Service Institution* (London).

TACUBAYA, tȧ'kōō-bä'yȧ. A Mexican town in the Federal District, the head of the prefecture of that name, three miles southwest of the City of Mexico (Map: Mexico, C 9). It is a fashionable suburb and is famous for its gaming establishments and handsome villas. It is pleasantly situated partly on a plain and partly on a hillside which is crowned by an ancient episcopal palace, now used as one of the national observatories. The population, in 1895, was 15,259.

TACUL'LI (Carriers). A tribe of Athapascan stock (q.v.) residing about Stuart and McLeod lakes, on the headwaters of the Peace and

Fraser rivers, in Central British Columbia. Their social organization was based on the clan system. Their canoes were neatly made from birch bark; they hunted during the winter season on snowshoes; and their women spun yarn from the hair of the mountain goat and also made a coarse pottery. They are all now Christianized through the efforts of French Catholic missionaries, who devised for their language a syllabic alphabet in which nearly all have learned to read and write, although they have no schools. They are gathered on small reservations, and they numbered about 750 in 1903.

The Déné syllabary, as it is called, is the invention of the Rev. Adrien Morice, who began his mission work among the Athapascan tribes of British Columbia in 1880. It consists of thirty characters, which by inversion of position and the use of accompanying dots or dashes can be made to indicate nearly two hundred distinct syllables or sounds common to the Taculli, Chilcotin, and other neighboring cognate languages. Its printed literature consists of text-books, religious works, and the *Carrier Review*, a monthly journal published by Father Morice at Stuart Lake.

TADEMA, tā'dĕ-mȧ, ALMA-. An English painter. See ALMA-TADEMA.

TAD'MOR. Another name for Palmyra (q.v.).

TADPOLE (ME. *tadpolle, taddepol*, from *tadde, tade*, toad, AS. *tādige, tādie*, toad + *polle*, head, poll). The larval form of anurous amphibians. For its metamorphosis see TOAD.

TAEL, tāl (Port. *tael*, from Malay *taïl, tahil*, weight, tael, from Hind. *tōla*, weight, from Skt. *tulā*, balance). The name commonly given to the Chinese *liang*, a money of account in China, and worth from .724 to .806 of an American dollar, but varying in value in different parts of the Empire.

TÆNIA. An animal parasite developed in the intestines of man and some animals. See TAPEWORM.

TÆ'NIOP'TERIS (Neo-Lat., from Gk. *ταινία, tainia*, band, ribbon + *πτερίς, pteris*, fern). A genus of fossil ferns found in rocks of late Paleozoic and Triassic age. They have long leathery fronds of linguate form with entire margins, a strong central rib, and numerous closely parallel veins that run at right angles from the midrib to the margins. The fruiting frond is not known. See FERN.

TAENSA, tä-ĕn'sȧ, or **TENSA.** An historic American Indian tribe living, when first known to the French, about the year 1700, in seven villages between the Tensas River and the Mississippi, in the present Tensas Parish of Louisiana, about 20 miles from Natchez. Like the neighboring Natchez (q.v.), with whom they seem to have been closely connected, they were sun-worshipers and kept a sacred fire constantly burning in a temple. A part of the tribe, driven out by the Chickasaw (q.v.), was afterwards colonized by the French on the west side of Mobile Bay, in the neighborhood of Mobile, Ala., where the local name still remains. The settlement contained one hundred cabins about 1750. At a later period they removed higher up the Alabama River near the site of the present Tensaw. They were probably merged finally into the Choctaw or the Creek Confederacy. Nothing is known positively of their language, the *Grammaire et vocabulaire de la langue Taensa* by Haumonte, published in Paris in 1882, having been proved to be a transparent fraud. According to contemporary French testimony, however, the language was cognate with that of the Natchez.

TAFFETA (OF., Fr. *taffetas*, from Pers. *tāftah*, taffeta, woven, p.p. of *tāftan*, to weave). A term of somewhat general application in silk manufacture. It was formerly applied to all plain silks simply woven by regular alternations of the warp and filling (see WEAVING), and is by some writers supposed to be the first kind of silk-weaving known even to the Chinese, from whom it came to us. Modifications have, however, been introduced, by varying the quality of the warp and filling, and by the substitution of various colors for the single one of the original taffeta. It has therefore become a sort of generic term for *plain silk*, and other silk fabrics, and even for some combinations of silk, wool, and other materials.

TAFFY. See NATIONAL NICKNAMES.

TAFILET'. A large oasis in the northwestern part of the Sahara, belonging to Morocco, and situated at the southern base of the Atlas Range, 200 miles south of Fez (Map: Africa, D 1). Area, about 500 square miles. The chief product is dates, but the oasis is mainly important as one of the principal trading stations between Morocco and the Sudan. The oasis includes about 150 towns and villages, the largest and the most important commercial centre being Abuam. Population of the oasis, about 100,000.

TAFT, LORADO (1860—). An American sculptor, born at Elmwood, Ill. He was educated at the University of Illinois (Champaign, Ill.) and at the Ecole des Beaux-Arts in Paris (1880-83). In 1886 he became an instructor at the Art Institute of Chicago, and in 1893 a lecturer in the university extension department of the Chicago University. His works include statues of Schuyler Colfax (Indianapolis) and of General Grant (Fort Leavenworth, Kan.), and the sculptural decorations for the Horticultural Building of the World's Columbian Exhibition (1893).

TAFT, WILLIAM HOWARD (1857—). An American jurist and administrator, son of Alphonso Taft, born in Cincinnati. He graduated at Yale in 1878, and at the Law School of Cincinnati College two years later. In 1881-82 he was prosecutor of Hamilton County, and later for a time was a collector of internal revenue. From 1887 to 1890 he was a judge of the Superior Court of Ohio, was Solicitor-General of the United States in 1890-92, and was a judge of the United States Circuit Court (sixth circuit) from 1892 to 1900, when at the request of President McKinley he resigned to become chairman of the commission appointed to establish civil government in the Philippines. The following year, on June 5th, he was appointed the first civil Governor of the islands. In 1903 Taft resigned this position to accept the appointment of Secretary of War, as successor of Elihu Root. Consult: *American Monthly Review of Reviews*, vol. xxiv. (1901); and *The Outlook*, vols. lxiv., lxix., and lxx. See PHILIPPINE ISLANDS.

TAGABALOYE, tä'gä-bä-lō'yĕ. A tribe of eastern Mindanao. See PHILIPPINE ISLANDS.

TAGABAWA, tä'gä-bä'wä. A mixed people in Davao Province, southern Mindanao. See PHILIPPINE ISLANDS.

TAGABELIE, tä'gä-bā'lē-ā. A wild Malay people in southern Mindanao. See PHILIPPINE ISLANDS.

TAGAL, tä-gäl', **TAGALA**, tä-gä'lä, **TAGALOG**, or **TAGALO**, tä-gä'lō. A Malay people of the Philippine Islands, having an alphabet and considerable culture in pre-Spanish times. They inhabit many provinces in middle Luzon, and form with the Ilocano (q.v.) and Visaya (q.v.) the bulk of the Filipino population. Their language and culture have spread among the other tribes. See PHILIPPINE ISLANDS; PHILIPPINE LANGUAGES.

TAGANROG, täg'an-rôg'. A seaport in the Province of the Don Cossacks, Russia, on the northern coast of the Sea of Azov, 18 miles northwest of the mouth of the Don (Map: Russia, E 5). The harbor has now become very shallow and the trade of the town is decreasing. The principal export is grain. The total trade in 1899 was about $1,800,000. The manufacturing industries are well developed and the principal products are flour and tobacco. Population, in 1900, 60,678.

TAGBÁNUA, täg-bä'nōō-ä. A Malay-Negrito people in Palawan Island and the Calamianes Archipelago. See PHILIPPINE ISLANDS.

TAGHKANIC (tä-kä'nĭk) **MOUNTAINS.** See TACONIC MOUNTAINS.

TAGLIACOZZO, täl'yä-kôt'sô. A town in the Province of Aquila, Italy, 24 miles east by north of Tivoli, near which, on August 23, 1268, Charles of Anjou decisively defeated Conradin of Swabia (q.v.), the last of the Hohenstaufen.

TAGLIONI, tä-lyō'nē. An Italian family of ballet-dancers, of whom FILIPPO (1777-1871) was the first to attain prominence. He was born in Milan, became ballet-master, successively, at Stockholm, Cassel, Vienna, and Warsaw, and composed many ballets, of which *Sylphide* is the most noteworthy. His daughter MARIA (1804-84), born at Stockholm, was connected successively from 1822 with the opera houses in Vienna, Paris, and Berlin, appeared with enormous success also on all the other principal stages of Europe, and in 1832 married Count Gilbert de Voisins. After her last appearance in London, 1847, she retired to Italy. Her brother PAUL (1808-84), born in Vienna, performed successfully at Stuttgart, Vienna, and Paris, and in 1829 secured a permanent engagement in Berlin, where he was appointed ballet-director of the Royal Theatre in 1869. As a composer of ballets he earned world-wide reputation, especially with *Flick und Flock* and *Fantasca*. His daughter MARIA (1833-91), born in Berlin, made her début (1847) in London, was for some time a great favorite at the Royal Theatre in Berlin, then at San Carlo in Naples, and married Prince Joseph Windischgrätz in 1866.

TAGOSATI, or **TOGASASTI**. A shrub (*Cytisus proleferus albus*) of the natural order Leguminosæ. It is a native of the Madeira and the Canary islands, where it is an important fodder plant and from whence it has been introduced into southern Australia. It is well adapted to dry soils and climates, but cannot be depended upon where there is danger of frost.

TAGUAN (East Indian name). A large Old World flying squirrel (*Pteromys petaurista*). See FLYING PHALANGER.

TA'GUS (Sp. *Tajo*, Port. *Tejo*). The largest river of the Iberian Peninsula. It rises in the Sierra de Albarracin on the western boundary of the Spanish Province of Teruel, 88 miles east of Madrid, and flows in a general west-southwest direction through Spain and Portugal, emptying into the Atlantic Ocean shortly after passing the city of Lisbon (Map: Spain, D 2). Its length is 565 miles. In its upper course it traverses the arid plains of New Castile, but at Toledo it plunges through a wild gorge between high granite cliffs. Farther west it again flows through sandy, level country, bordered by oak forests. About 40 miles above Lisbon it divides into two branches, which inclose a low, marshy island, and which reunite in the Bay of Lisbon, an expansion of the river about 18 miles long and 5 miles wide. This bay is deep and sheltered, and forms one of the best harbors in the world. At Lisbon the river again contracts, and enters the ocean through a narrow and deep channel, which, but for the bar at the mouth, would be accessible for the largest ships. The river is regularly navigated 105 miles to Abrantes, but in Spanish territory navigation is impeded by rapids.
